Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test¹⁻¹⁰ Reed¹¹ in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

When the stagnant sinus must be drained...

Transillumination of the sinuses — diffuse shadow on right side of face indicates unilateral maxillary sinusitis.

In the common cold, Neo-Synephrine is unsurpassed for reducing nasal turgesence. It stops the stuffy feeling at once. It opens sinus ostia to re-establish drainage and lessen the chance of sinusitis. With Neo-Synephrine, in the concentrations most commonly used, decongestion lasts long enough for extended breathing comfort, without endangering delicate respiratory tissue. Systemic side effects are virtually unknown. There is little rebound tendency.

Neo-Synephrine[®] HCl

Brand of phenylephrine hydrochloride

is available in a variety of forms,
for all ages:

- 1/8% solution for infants
- 1/4% solution for children and adults
- 1/4% pediatric nasal spray for children
- 1/2% solution for adults
- 1/2% nasal spray for adults
- 1/2% jelly for children and adults
- 1% solution for adults (resistant cases)

Also NTZ[®] Solution or Spray
Antihistamine-decongestant

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

'Thorazine' is useful as a specific adjuvant in the above named conditions.

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*. **Contraindications:** Comatose states or the presence of large amounts of C.N.S. depressants. **Precautions:** Potentiation of C.N.S. depressants may occur (reduce dosage of C.N.S. depressants when used concomitantly). Antiemetic effect may mask other conditions. Possibility of drowsiness should be borne in mind for patients who drive cars, etc. In pregnancy, use only when necessary to the welfare of the patient. **Side Effects:** Occasionally transitory drowsiness; dry mouth; nasal congestion; constipation; amenorrhea; mild fever; hypotensive effects, sometimes severe with

I.M. administration; epinephrine effects may be reversed; dermatological reactions; parkinsonism-like symptoms on high dosage (in rare instances, may persist); weight gain; miosis; lactation and moderate breast engorgement (in females on high dosages); and less frequently cholestatic jaundice. Side effects occurring rarely include: mydriasis; agranulocytosis; skin pigmentation, lenticular and corneal deposits (after prolonged substantial dosages).

For a comprehensive presentation of 'Thorazine' prescribing information and side effects reported with phenothiazine derivatives, please refer to SK&F literature or *PDR*.

Smith Kline & French Laboratories 

President's Letter

MY "MAIDEN EFFORT" at writing this President's letter to all of you concerns a subject which should be of great interest to each of us. I am referring to the debate which is currently going on regarding the real value of our annual MSMA meeting in May. The attendance has been dropping off the last few years, and the meeting was cut from three days to two.

There is no doubt in all of our minds, however, that some overhauling is due. There are two committees of your association which are working on this problem. One of them is the ongoing Permanent Evaluation Committee, whose Chairman is Past President Haddon Carryer of Rochester. This committee has recommended a two and one-half day session, rather than the shorter two day meeting. The House of Delegates will meet on Sunday, as usual, and again on Tuesday for its final session. There will be committee breakfasts on Monday, Tuesday, and Wednesday mornings, where desired.

The other committee, which has put much time and thought into the program section, is the Committee on Scientific Assembly. It has come up with a whole format for this coming May meeting. The reasons for this are many. There is much more competition today than in years past for the physician's time spent in postgraduate study. There are at least two other very excellent meetings held near the time of the State Meeting, with which we must compete. This competition is good for us, as we are being forced, as it were, into creating a better meeting.

Your Committee on Scientific Assembly

has made several big changes. There will be seven major topics discussed in depth, for one to one-and-a-half hours each, with time for questions. There will be the usual break between sessions for viewing of the scientific and commercial exhibits. There will be one entirely new (to many of us, at least) period with 10 short subjects being presented at 5 minutes each. These will be "tricks of the trade" talks entitled "How to do it" topics such as the plugged catheter, the bloody nose, warts, etc. These are the common "garden variety" problems which most of us see every day, and which can be very vexing to handle.

Dr. Arthur C. Aufderheide and some of his colleagues in Duluth are going to innovate a program on Erythroblastosis which will involve some preliminary study by those who are interested and sign up for the course in advance of the meeting. The possibilities offered here sound exciting, indeed.

The last session, Wednesday morning, will be devoted to the Socio-Economics of Medicine, which are of such great interest to all of us today. This program has not been worked out, as it is much too early to do so. Our own State Legislature, as well as the 90th United States Congress are now in session, and events can change rapidly in this area. For this reason no agenda can be worked out that would be meaningful, until the last minute.

All of your officers, councilors, and committees urge you to attend as many of the sessions as you can; we want you to see that

Criminal Abortion

Deaths
and
Suicides
in
Pregnancy
in
Minnesota,
1950-1964*

ALEX BARNO, M.D.
St. Louis Park, Minnesota

BECAUSE THE recent lay and medical literature^{1,2,3} is being bombarded with the repetitious figure of 5,000-10,000 deaths annually in the United States from criminal abortion, it was decided to test the reality of this figure as it pertains to the State of Minnesota. Also, since the most frequent psychiatric indication for therapeutic abortion is the fear of the patient committing suicide, the problem of suicide in pregnancy is included in this report. The material herein is from the Minnesota Maternal Mortality Study for the 15-year period, 1950 through 1964. The mechanics of the study need not be repeated since it is known to the physicians of the state. This has been a continuous study since 1950 and previous reports have been published.

Criminal Abortion Deaths

During the period of this study there have been on the average 4,000,000 live births annually in the United States, to which Minnesota has contributed an average of 80,000 annually, or 1/50th of the total. As has been reported, the crusaders for the liberalization of therapeutic abortion have published the repetitious figures of 1,000,000-1,500,000 criminal abortions being done annually in the United States with 5,000-10,000 deaths resulting. If Minnesota contributes 1/50th of the birth rate annually, it should contribute 1/50th of the annual criminal abortion deaths. One fiftieth of 5,000 is 100 and 1/50th of 10,000 is 200. However, as will be shown later, instead of 100-200 criminal abortion deaths annually in Minnesota, there have been 20 in 15 years or 1 per year. Where are the other 99 or 198? We can't find them in the Minnesota

*From the Minnesota Maternal Mortality Study.

Part of the Symposium on Therapeutic Abortion read at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, April 23, 1966.

Requests for reprints should be addressed to the St. Louis Park Medical Center, 4959 Excelsior Blvd., Minneapolis, Minnesota.

Maternal Mortality Study, which is as accurate a study as any in the nation. There is no doubt that we are missing some, but we certainly are not missing 99 or 198 per year. What is the source of these figures being reported? The physician and lay criminal abortionists have not published their figures as yet. Therefore, either the professional competence of the criminal

abortionists has been seriously underestimated or else these figures have been grossly exaggerated. The latter seems the more probable. In any event, the death rate due to illegal abortion can be decreased only by allowing legal abortion to any woman who asks for it. But most physicians certainly would see no medical reason to do so.

In Table 1 are shown the Minnesota Maternal Mortality rates and preventability for 1941 and the years under discussion. Since 1960 the live births have decreased yearly. The corrected maternal mortality rate has remained at 0.1 to 0.2 per 1000 live births during the last eight years, which seems to be an irreducible minimum and speaks well for the physician care of the obstetric patient.

Infection and Air Embolism

Table 2 summarizes the 370 obstetric causes of death. The criminal abortions are in the infection and air embolism categories. The totals for each category were 11 and nine respectively. These will be discussed subsequently in more detail. Of the 11 air embolism deaths, two were due to air being pumped in under pressure during blood transfusion by R.N. anesthetists at surgery.

Overhydration with water intoxication (1)	—	—	—	—
Unexplained shock (1)	—	—	—	—
Totals	370	100	138	99

The other nine were criminal abortions (catheter inserted into the uterus). All of them had autopsies.

Suicides

Under "others" category are listed three suicides from post-partum psychosis. During the first few years of the study the Maternal Mortality Committee tried to assess psychiatric disease as obstetrical versus non-obstetrical. If the mental aberration occurred before pregnancy the disease was assessed as non-obstetrical. If it occurred during pregnancy or post partum, the disease was assessed as obstetrical. This concept was later discontinued and all the suicides were included in the trauma category as violent deaths in the non-obstetric causes.

For completeness the 260 non-obstetric causes of death are tabulated in Table 3. The other 11 suicides are included in the trauma category. Thus there were a total of 630 maternal deaths among 1,232,545 live births during the 15 years under consideration.

Illegitimate Live Births vs. Illegitimate Maternal Deaths

Table 4 correlates the illegitimate live births with illegitimate maternal deaths. The illegitimate live births have more than doubled during the last 15 years. Are we going to solve this problem by aborting all of them as some would advocate? Psychiatrists, psychologists, social workers, theologians, parents and others have been groping with this problem since the beginning of time and it is still with us. If all 3,655 illegitimate live births had been aborted therapeutically early in pregnancy in 1964, it would be safe to assume that there would have been twice this number to perform in 1965.

There were a total of 38 maternal deaths among 33,620 illegitimate live births with 11 of these being criminal abortion deaths. These are analyzed in more detail in Table 5. The criminal abortions comprised one half of the obstetrical causes of death. A word is in order regarding the four homicides under the non-obstetrical causes. Two of these were perpetrated by the consort because

the patient refused to marry him; one was perpetrated by the consort because he refused to marry her; and the other case was a divorcee who accused a married man of being the father of the child with the result that she was strangled by him.

Table 6 is a breakdown of all of the criminal abortion deaths. These were almost equally divided between the illegitimate and legitimate pregnancies. As to causes, they were also almost equally divided between

septic abortion and air embolism. Thus there were a total of 20 among 1,232,545 live births or one per every 61,627 live births. It is interesting to note the method used for the abortions. In seven instances the catheter was used; in seven the method was unknown. The other methods were as follows: rubber tubing, syringe with solution of soap and turpentine, glass straw with bulb syringe and soap and turpentine, plastic tube with soap solution, tap water douche under high pressure and nut pick. The bacteriology of the septic abortion deaths has been published previously.⁴

Suicides

As the medical indications for therapeutic abortion have dwindled to almost nothing, the psychiatric indications have risen. Simon⁵ states that as many as 80 per cent of therapeutic abortions are for psychiatric reasons. Gold⁶ from New York City for a three-year period, 1960-1962, reported that 61 per cent of the therapeutic abortions were done for psychiatric indications. Since the principal criterion for psychiatric recommendation is the likelihood of suicide, it was decided to investigate the reality of this from the Maternal Mortality data.

Table 7 shows the deaths and death rates due to suicide in Minnesota residents. As can be seen, males kill themselves four to five times more frequently than females. There were a total of 14 suicides in the obstetrical patient. Not a single one of these women was illegitimately pregnant. Not a single one requested a therapeutic abortion. Suicide in pregnancy is rare — 0 to 0.1 per 100,000 population. Expressed in another manner, there were 14 among 1,232,545 live births or one per every 88,035 live births, slightly less than one per year. Perhaps pregnancy has a psychically protective role.

As explained earlier in this paper, most of the suicides (11) were placed in the trauma category (Table 8). With the other three in the obstetrical category, this made a total of 14. The other trauma deaths are self explanatory.

Table 9 shows a more detailed analysis of the 14 suicides. Regarding parity, four

CRIMINAL ABORTION — BARNO

were primigravidas and the remainder multiparas. It is interesting to note that 10 committed suicide post partum and only four with the fetus in utero, or one per every 308,136 live births. The fetus in utero must be a protective mechanism; it is conceivable that women are reluctant to take another life with them. A psychiatrist-consultant, after studying the 14-case history protocols, made the diagnoses as listed. There were 12 psychotic depressions and two schizophrenics. Only four of the total of 14 had seen a psychiatrist for help. The family, the family physician and the obstetrician were remiss in seeking psychiatric help. The method of suicide is tabulated and is self-explanatory.

Other studies have also shown that suicide in pregnancy occurs rarely. Höök⁷ in Sweden in 1963 published a 7½-11-year follow-up study of 249 women who in 1948 were refused a legal abortion. Of the 249, 86 per cent continued the pregnancy and delivered, 3 per cent had a spontaneous abortion and 11 per cent had an illegal abortion. There were no suicides or suicide attempts in any of these even though seven had attempted suicide in the non-pregnant state.

How can pregnancy cause such a psychiatric upheaval or turmoil as to alter the psychodynamics of an individual to the extent that she will commit suicide? If she does not do so, psychiatrists tell us that she will be very unhappy or upset. This

seems a most nebulous, non-objective, non-scientific approach to medicine. Are we all happy and serene all of the time or even

TABLE 7

most of the time? Isn't there some unhappiness and turmoil in all of our lives? It would seem that the psychiatrists could be accomplishing more by treating or rehabilitating the patient instead of recommending the destruction of another human being. It would also seem that a better solution to this whole problem might be one of prophylaxis — more use of available contraceptive agents and a more liberal sterilization policy.

Summary and Conclusions

1. The Minnesota situation with regard to maternal deaths due to criminal abortion and suicide in pregnancy has been reported for the 15-year period, 1950-1964.

2. The repetitious figures of 1,000,000-1,500,000 criminal abortions annually in the United States with 5,000-10,000 deaths that are bombarding the medical and lay literature are inaccurate. It has been shown that if they were true, Minnesota should be having 100-200 criminal abortion deaths annually. In reality, Minnesota has one criminal abortion death yearly (20 during the 15-year period).

3. As to cause of death, the 20 criminal abortion deaths were almost equally divided between septic abortion and air embolism and between illegitimate and legitimate pregnancies.

4. The death rate due to illegal abortion can be decreased only by allowing legal abortion to any woman who asks for one. Most physicians certainly would see no medical reason for this.

5. As the medical indications for therapeutic abortion have dwindled to almost nothing, the psychiatric indications have risen — 60-80 per cent of those being done at the present time.

6. Psychiatrists use the likelihood of suicide as a danger to the life of the mother as the principal criterion for psychiatric recommendation for therapeutic abortion. This is not being realistic.

7. There were only a total of 14 suicides in the obstetrical patient among 1,232,545 live births or one per 88,039 live births. This was less than one per year. Expressed in another manner, the rate varied from 0 to 0.1 per 100,000 population as compared to 3.1 to 5.2 per 100,000 population of all females.

8. Not a single one of the suicides was illegitimately pregnant and none requested therapeutic abortion.

9. Of the 14 suicides, 10 occurred during the post-partum state and only four with the fetus in utero. Perhaps pregnancy has a psychically protective role.

10. Regarding the psychiatric diagnoses, 12 were psychotic depressives and two were schizophrenics.

11. Only four of the 14 had seen a psychiatrist for help. The family, the family physician and the obstetrician were remiss in seeking psychiatric consultation.

The author acknowledges with gratitude the assistance of Mr. E. W. Storey, Research Analyst, Section of Vital Statistics, Minnesota State Board of Health, for the statistics regarding illegitimate live births and the death rates due to suicide.

On Quaffing

The great Canadian physician Sir William Osler was lecturing one day on alcohol. "Is it true," asked a student, "that alcohol makes people able to do things better?" "No," replied Sir William. "It just makes them less ashamed of doing them badly."

Abortion Laws*

Inequitable,
Inconsistent
and
Hence
Inexcusable

FRED A. LYON, M.D., F.A.C.O.G.
Minneapolis, Minnesota

THE PRESENT practice of performing therapeutic abortions in the United States is inequitable, inconsistent and hence inexcusable. The medical and legal professions share the responsibility for creating this situation and therefore should accept the responsibility for correcting it.¹ It is known that the medical profession cannot and will not dictate abortion policies. Neither can the legal profession dictate abortion policy. It is undeniable that at the present time the abortion laws are flagrantly flouted, much more often for the rich than for the poor. This situation is unacceptable to many practicing physicians since it makes hypocrites out of them and forces them to care for their patients in a manner which many times is in conflict with sound medical practice in many reputable hospitals. Since it is primarily the obstetrician who is concerned with circumventing these antiquated abortion laws it ought to be the obstetrician who should seek their modernization.

Abortion Laws in Minnesota

Minnesota is one of nine states which in its statute mentions that an abortion is allowable if it is performed to save the life of either the mother or the child.² The latter phrase is included because of the concern about abortion prosecutions arising out of instances where a doctor decides that premature labor must be induced.

In 1963 a legislative committee of the state legislature heard the following proposal as part of the Proposed Minnesota Criminal Code Revision, "... that therapeutic abortion be deemed justified when it is performed by a physician and performed in a licensed hospital if any of the following conditions exist: Rape, when it is necessary to save the life of the mother, or avoid grave impairment in the physical or mental condition of

*Part of the Symposium on Therapeutic Abortion read at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, April 23, 1966.

the mother, or to prevent the birth of a child with grave physical or mental defects. This procedure should be approved by two other physicians."

Abortion Laws in the United States³

All of the 50 states have statutes indicating severe penalties for criminal abortion. With one or two exceptions, each state has recognized necessity as a justification for therapeutic abortion.*

American Law Institute Proposal

The American Law Institute is a group of eminent jurists, lawyers and professors of law who make occasional proposals to update antiquated laws in the United States. These men are highly respected for their opinions and are adequately qualified to make their recommendations. In 1959, they recommended in their Model Penal Code that abortion laws should be modified.*

Acceptance Proposal by Organized Medicine and the Laity

In 1964 a questionnaire was sent out to 2,285 obstetricians and gynecologists in the state of New York asking for their views on the acceptance or rejection of the American Law Institute proposal as it relates to the performance of therapeutic abortion. The following results were obtained:⁷

Number in favor	1,152	85.3%
Number opposed	198	14.7%
Replies received	1,350	62%

The Committee on Human Reproduction of the American Medical Association recently recommended approval almost verbatim of the Model Penal Code of the American Law Institute.⁸ As a result of the recent California legal action against prominent obstetricians for performing therapeutic abortions, many outstanding obstetricians and lawyers have gone on record as approving a revision of the law. Numerous medical and legal societies have approved such action. The New York Academy of Medicine, The California Medical Association's House of Delegates, The California State Department of Public Health, The California State Board of

Health, the main obstetrics and gynecology societies of California, the Medical Society of the County of New York, the New Jersey Branch of the American Medical Women's Association and many leading obstetricians and gynecologists⁹ in the United States have all urged reform of the law in accordance with the Model Penal Code of the American Law Institute. Professor Nicholson Eastman's⁹ only objection to the American Law Institute proposal is based on the use of the word "believes." He states that a "belief" that an abortion is necessary is not enough and that there exists the possibility that unscrupulous physicians will pervert the law, and he proposes that in addition to the Model Penal Code recommendation a therapeutic abortion committee be established in each hospital and that to this committee be given the responsibility of approving or rejecting the request, in order to prevent the "double standard" in respect to indications for abortion . . . a liberal one for private patients and a much more stringent one for ward patients. Professor Eastman further states that the fact that law enforcement agencies seem to condone the violation of our present abortion laws only serves to stress the inconsistency of the situation.

Unrealistic Laws

It becomes perfectly obvious that these laws are recognized as unrealistic by prominent members of the legal profession as shown by the 1959 recommendation of the American Law Institute. That these laws are felt to be unrealistic by medical groups and individuals seems perfectly clear. That the laity knows these laws to be unrealistic is documented by the fact that 20% of all pregnancies are illegally aborted.^{1,4,5,8} A recent Gallup Poll¹⁰ reported that the effort of the A.M.A. to get states to adopt a uniform and liberalized abortion law is looked upon with favor by a majority of those interviewed. Nearly 80% of adults favored legalizing abortion when a mother's health is endangered and 54% when the child might be born deformed. Substantial majorities of both Catholics and Protestants favored the former; however, when a child might be born with a physical or mental deformity, 46% of Catho-

*See "It's the Law" page 45.

lics and 56% of Protestants were in favor of abortion.

It seems clear that if the medical and legal profession fails to assume the leadership necessary to change the existing laws, it will only be a matter of time before an informed and outraged public will demand the necessary alterations and renovations of the law. People are asking, "How many more women must be sacrificed to needless suffering and death before changes are made?"¹¹

World Wide Trends in Abortion¹¹

In the Scandinavian countries the abortion laws have been liberalized for some time. Recent statistics reveal the following information:

Incidence of Abortion

Country	Year 1940	Year 1956	Total Increase
Denmark	0.7%	6.0%	9 fold
Sweden	0.5%	3.5%	7 fold

Number of Abortions Per Year

Sweden	Rate/1,000 live births (1957-60)	3,000	27-32
Denmark		4,000	49-54

Switzerland recently reported that one therapeutic abortion is done for every 15 live births.¹¹

Japan in 1949 reported 2.69 million births and the abortion rate was 91/1,000 live births.

Year	Abortion Rate/1,000 Live Births
1949	91
1957	716
1961	653

Total live births decreased to 1.56 million. Total abortions done in last 15 years: 20,000,000.

In *Poland*, a recent paper reported on 561,000 abortions done with a mortality rate of 1/40,000 pregnancies and a very low morbidity rate.¹² When the opponents of abortion speak about the grave risks to which pregnant women are exposed at the time of a therapeutic abortion they ought to remember that in 1963 alone, 975 patients were admitted to the New York Metropolitan Hospital with serious complications arising from septic, criminal abortions.¹³ In Poland legal abortions are being done at the rate of 700,000 per year.¹³

In our hemisphere, *Chile* reports one abor-

tion done for every live birth, an increase from 1950-1954 when of every 100 women admitted for delivery in a hospital, 85 were admitted for abortions.¹¹ At one time in Chile 40% of all of Chile's hospital beds were filled with women who had infections as a direct result of criminal interference with pregnancy. In Uruguay there are two to three abortions for every live birth.¹³

Great Britain is at the present time almost certain to pass an "Abortive Bill" very similar in content to the recommendations of the American Law Institute.¹⁴ It has been estimated that £175,000 worth of National Health Service bedspace each month is occupied by septic abortion cases. In a London hospital, for every patient admitted for a therapeutic abortion, 50 are admitted as a result of criminal abortion.

Definition of the Problem in the United States

Criminal Abortion

In the United States alone it has been estimated that between 1,000,000 and 1,500,000 criminal abortions are done yearly.^{4,18} The number of deaths due to such abortions per 10,000 live births has doubled in the last 20 years from 1.6 to 3.1.¹⁶ It is known that between 5,000 and 10,000 women die each year in the United States from infections and injuries accompanying criminal abortions.^{4,15} Each day an average of 10 patients suffering from the effects of illegal abortions are seen at the Los Angeles County Hospital. Abortion is the single, largest cause of maternal death in California. While deaths from other causes have markedly declined, the death rate from abortion has remained static. The absolute number of deaths from abortion has doubled.¹⁷ The reduction of deaths from illegal abortions presents the greatest opportunity for reducing the over-all maternal mortality rate.

When one considers that not many more women die each year in this country from cervical cancer it becomes apparent that the deaths from illegal abortion are a major public health problem. It becomes perfectly obvious that physicians are willing to forget these women in favor of spending large sums

of money for such worthwhile projects as cancer detection, diabetes detection and tuberculosis detection and control. These women are forgotten because many people still think of desperate women with unwanted pregnancies, married or single, as promiscuous and demand that they be punished by society for their "wrongful" acts.

Therapeutic Abortion for Rubella

Total number of therapeutic abortions in U. S./year: 8,000-10,000.

In 1964, an epidemic year for rubella, in Buffalo, New York, rubella accounted for 36% of the indications for the therapeutic abortions done. About 20,000 malformed babies were born as a result of that epidemic or roughly 4-5 times as many as in the recent Thalidomide disaster. One wonders what it takes to shock people.¹⁵

It is stated that the over-all incidence of therapeutic abortion in the United States is one in 400-500 deliveries.

Place	Year	Number of Births or Deliveries ¹	Incidence
California	1952-56	224,823 deliveries	1/418
N.E. U. S. A.	1959	44,439 live births	1/463
N. Y. City	1960-62	499,927 live births	1/555
61 U. S. Hosp.	1963	522,578 deliveries	1/503

The over-all therapeutic abortion rate¹ in the United States is falling.

Place	Year	Ratio of Abortion/Births or Deliveries	
N. Y. City	1943-47	1/196 live births	} decrease of 65% in 20 yrs.
	1951	1/344	
	1960-62	1/555	
Mayo Clinic	1945-49	1/173 deliveries	
	1950-54	1/292	
Univ. of Virginia	1941-45	1/85 deliveries	
	1946-50	1/119	
	1951-52	1/337	
Sloane Hosp. for Women, Columbia U.	1950-55	1/69 deliveries	
	1956-60	1/225	

In New York City alone, the decline is about the same, in the range of 65%. During the years 1951-1962 the over-all frequency of therapeutic abortion in New York City declined by 50%.¹⁶

Year	Number of Therapeutic Abortions	Ratio/1,000 Live Births
1943-47	3,592	5.1
1949	668	4.3
1951-53	1,698	3.5
1954-56	1,096	2.2
1957-59	1,034	2.1
1960-62	875	1.8

Although the over-all frequency of therapeutic abortion has markedly declined, the "double standard" spoken of by Professor Eastman has become more apparent. The disparity between ethnic groups and socioeconomic levels on the one hand and the availability of therapeutic abortion has in fact widened.¹⁶ For example:

Sloane Hospital, New York City ⁷	
Ratio of private/ward patient: 4:1	
60 U. S. Hospitals, 1963	
Ratio of therapeutic abortions/live births: ⁷	
Proprietary Hospitals: 1/256	
Private service voluntary hospitals: 1/416	
Ward service voluntary hospitals: 1/1,429	
Municipal Hospitals: 1/10,000	
Obstetrical Cooperative (11 Eastern Hospitals), ¹⁹	
Therapeutic abortion rate: White patients 2.9/1,000 live births	
Colored patients 1/13,000 live births	
Sloane Hospital, New York City ⁸	
Private patients 1/55 deliveries	
Ward patients 1/224 deliveries	
Type of Institution	Frequency
Proprietary hospital	6.3/1,000 live births
Private service, vol. hosp.	3.6/1,000 live births
Ward service, vol. hosp.	1.9/1,000 live births
Municipal hospital	1.2/1,000 live births

Therapeutic abortion among white patients is more than five times as common as among non-whites and twenty-six times as common as among Puerto-Ricans.¹⁸ It becomes perfectly obvious that the affluent woman is much more likely to be aborted than her indigent sister. There is a downward trend in all therapeutic abortions, but it is greatest among Puerto-Ricans, less among non-whites and least among whites. About 90% of all the therapeutic abortions performed are done on white women.¹⁶ When considering deaths from criminal abortions, however, the converse is true.

Deaths From Criminal Abortions		
Race	10,000 Live Births 1945-65	
White	0.6 to 1.0	
Non-white	6.1 to 8.0	
Puerto-Rican	4.0 to 4.7	

It is seen, therefore, that as a result of denying therapeutic abortion to certain races

many more women die each year from the effects of criminal abortion. Not only is affluence a factor in being able to procure an abortion legally, but race and nationality play a significant role as well. We need, therefore, to equalize the opportunities for therapeutic abortion regardless of socioeconomic status, race, nationality and hospital service.

When one examines these inequalities in terms of the type of patient admitted to a particular hospital and the indications for abortion, the following is evident:¹⁶

Therapeutic Abortion, By Indication And By Type Of Care
N. Y. C. 1954-62

Indication	Prop. Hosp.	Pvt. Serv.	Ward Serv.	Municip. Hosp.

Therapeutic Abortion for Mental Disorders

It is interesting to note that mental disorders account for $\frac{2}{3}$ of the abortions done in proprietary hospitals, more than $\frac{1}{2}$ in the private services of voluntary hospitals and only $\frac{1}{3}$ in the ward services of voluntary and municipal hospitals. Ten times as many private patients have abortions done for psychiatric indications than clinic patients at Sloane Hospital for Women in New York City.¹ It is also well known that sterilization accompanies therapeutic abortion more than twice as often on the ward service whether the indication is medical or psychiatric.¹ Prior to 1950, psychiatric indications accounted for less than 20% of the therapeutic abortions done and since 1950, for 25 to 45%. This is an absolute as well as a proportionate increase. In New York City the number of therapeutic abortions over the last 10 years has declined steadily, but the per cent of therapeutic abortions done on psychiatric in-

dications has remained static, about 50%.²²

Psychiatric indications are given for nearly 94% of abortions done on unmarried women but for only 50% on married ones. The psychiatric criterion applies much more often to patients under 20 years of age and to those older than 39 years than to those in between.^{15,18} This correlates perfectly with the observation that abortion is most common early and late in the reproductive cycle of women. It seems that abortions for psychiatric reasons are almost exclusively the luxury of the rich. Abortion and psychiatric consultation are less common among the poor because they cannot afford them, they cannot find them, they are unaware of their benefits and they are less often referred for them by other physicians.¹

Contrary to general opinion, illegal abortion is more often a problem in the married woman with several children and less a problem in the single girl. The more children a woman has the more likely she is to seek an abortion. A much higher rate of criminal abortion occurs at younger ages and again later in life.⁴ The higher the educational level the greater is the tendency to seek an abortion. Astounding is the statistic that well over 80% of all pregnancies are criminally aborted in the unmarried college graduate.⁴ In the 1940s, almost no woman under 20 years had a legal therapeutic abortion, while in the 1960s such girls made up 12% of the total group. The nulliparous groups of patients increased from 20 to 40% of the total group. In the 1940s fewer than 10% of the women were unmarried; 40% are now single, widowed or divorced.^{15,18}

Discussion

It is obviously not the intent of any body of law to punish women with the risk of death for having illegal abortions; but this is the result. The present laws are supposed to protect the prospective mother and her unborn infant, but because the laws are too restrictive they discourage rather than encourage what is considered to be good medical practice. These laws undoubtedly drive many desperate women into the hands of the unskilled abortionist, the very man we wish to

protect them against. These same restrictive laws make it a certainty that only women in favored economic circumstances are able to procure safe termination of pregnancy, while those less fortunate, through no fault of their own, are forced to submit to the abortionist.

From what has been presented it is clear that more than 90% of the therapeutic abortions done at a large metropolitan eastern hospital do not fall strictly into the statutory requirements to "preserve the life of the mother."¹ Thus we become hypocrites who preach one thing and practice another. No one is content with breaking or circumventing the law . . . it behooves us therefore to use our influence to change the law.

No one should delude himself into thinking that modification of our present laws will eliminate criminal abortion. As long as there are restrictions, desperate women will find illegal abortionists. This is no reason, however, to abandon all attempts to correct these evils.

Kummer states that the forces in our society opposing abortion are well known and most obvious. What is also obvious is that these same social forces have not accomplished their stated goals, namely, maintaining morality and preventing abortion, injury and death.⁴ Some people are of the opinion that abortion, under any circumstance, is against morality. Those holding this view have every right to do so and can regulate their conduct in accordance with their beliefs. They must not, however, be allowed to impose their view on others who do not share it. This type of morality is subject to sharp dispute. Our present law prevents all physicians from performing an occasional indicated therapeutic abortion. The revised law would make therapeutic abortion legal; those who are not opposed can do such an abortion in full view of the law while those opposed need never per-

form such an act if they consider it immoral.

To those who say that by therapeutically aborting women with psychiatric illness the physician may be guilty of destroying brilliant offspring, it seems much more likely that the chances are far greater that he would be preventing countless heartaches and anguish. Those women aborted because they do not wish to risk producing a child with congenital deformities can always become pregnant again and bear normal, healthy children. To those physicians who say that all women illegitimately pregnant want to be pregnant, or who say that there are no psychiatric indications for therapeutic abortion and that by aborting medically and psychiatrically-ill patients physicians will only produce more psychiatric illness, it has been shown that moderate to severe psychiatric sequelae of induced abortion are indeed rare.²⁰ There is, on the contrary, a substantial incidence of post-partum psychiatric illness which accounts for 2% of female admissions to mental hospitals. To those who say that pregnant psychiatric patients rarely commit suicide, it seems clear that by driving these women to illegal abortionists one is flirting with death as well. It is obvious that psychiatrists are not always able to distinguish those patients who will or will not commit suicide; therefore, mistakes will be made on both sides. Since it has been shown that psychiatric indications for abortion are the largest single indication, it is clear that this is a game being played by both the psychiatrist and the obstetrician.

Only good can come from public discussion of these issues. It should be repugnant to physicians and lawyers that this kind of a dual standard for affluent and poor, black and white, should continue. When one considers that 1 to 1.5 million women resort to criminal abortion in the United States per year it speaks rather poorly for our concern for the welfare of all of our citizens.

An Obstetrician's View*

of Therapeutic Abortion

ERICK Y. HAKANSON, M.D.**
St. Paul, Minnesota

DURING THE past 30 years the incidence of induced abortion in the civilized world has risen progressively, resulting in enormous loss of life and health.

I think it is relevant to inquire briefly into the experiences of other countries before we review the facts that are available in our own country.

Legal Abortion

Outside the United States

Scandinavian medical literature provides the most comprehensive and best documented source material regarding therapeutic abortion. Strictly defined, the humanitarian and eugenic indications are considered as well as medical ones. However, an abortion is strictly under independent medical control and is not considered easy to obtain. The abortion rate in Sweden, in recent years, is approximately 3/100 term deliveries. Swedish authorities are concerned with the increasing number of its citizens who have been traveling to eastern European countries to get abortions. It is extremely difficult for a foreigner to get an abortion in Scandinavia.

Abortion became available in Eastern Europe in 1955-1957 on request for broadly interpreted social indications. Figure 1 shows that the number of induced abortions increased significantly, and in the case of Hungary in 1959, the number of abortions actually exceeded the number of births. It should be pointed out here that comprehensive family planning programs are just getting started in these countries.

In *Switzerland* there are 60-70 induced abortions for every 100 births, and two thirds of the abortants are married; the vast majority are healthy upper middle class mothers with small families.¹ Seventy per

*Part of the Symposium on Therapeutic Abortion read at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, April 23, 1966.

**Head, Department of Obstetrics and Gynecology, Saint Paul-Ramsey Hospital.

cent of the abortions are performed for psychiatric reasons, many of the abortants coming from other Western European countries.

Abortion has a very long cultural tradition in *Japan*, but it was not made legal and put under medical control until 1949. In that year Japan reported 2.69 million live births and 91 induced abortions/1000 live births. In 1957 the abortion rate had increased to 716/1000 live births, while 1.56 million births were recorded. The birth rate fell from 34.2 to 17.4/1000 population during that time. Japanese authorities feel that the number of reported induced abortions represents 50-60 per cent of the actual total.²

†Gold, et al.: Amer J Pub Health 55:964, 1965.

We are all familiar with the large traffic in abortions in *Mexico and Puerto Rico*, a significant number, perhaps a majority, of these being performed on Americans.

Mortality

Hungary has reported a mortality rate for 1960-1962 of 5/100,000, more than half of the fatal abortions performed after the first trimester.³ Ninety-nine per cent of therapeutic abortions in Hungary are done during the first trimester. Scandinavian countries report a mortality rate of 64-68/100,000; but bear in mind that the indications are stricter, and, more importantly, therapeutic abortion can be carried out as late as 24 weeks. Approximately 25-35 per cent are done after the third month, and this group carries a disproportionate share of the mortality. Tietze quotes a mortality rate for therapeutic abortion in New York City for 1943-49 of 230/100,000.⁵ For comparison, the mortality rate for tonsillectomy in the United States is estimated at about 17/100,000 (1959).⁴

In the United States

Figure 2 illustrates that over the past twenty to twenty-five years there has been a steady decrease in the incidence of therapeutic abortion, and it reveals how the various indications have participated in the over-all decrease in therapeutic abortion. With the exception of mental disorders, rubella, malignant neoplasms, and perhaps Rh incompatibility, there has been a drastic reduction in the frequency of all medical indications.

Doctor Lyon* has amply demonstrated the *disparity in incidence* of therapeutic abortion between private and charity patients, and points out that the nonwhite is much less likely to get a therapeutic abortion than her white sister. On the other hand, deaths due to induced abortion in the poor nonwhite make up a majority of their maternal deaths.⁶

Gold et al. have shown that the incidence of abortion is directly *related to the age of the patient*, being significantly more common at the end of the reproductive career. This correlation is not influenced by parity.⁶

There is some evidence to indicate that the number of total induced abortions has an additional peak in the early years as well as in a better-educated, suburban white population sample.⁷

Briefly summarized, therapeutic abortion is *not routinely advocated for any category of disease*, but only after adequate workup can reasonably document that there exists a substantial risk to the individual patient's life or to her health.

From the results of the survey of metropolitan hospitals in Minnesota* one could conclude that therapeutic abortion is a rarity. More likely therapeutic abortion is more often performed than coded on the face sheet. My guess would be that less than 50 per cent of the total therapeutic abortions were specifically coded as such.

Indications

While there has been an impressive decrease in the number of therapeutic abortions in most categories, there has been an increase for so-called fetal indications,⁸ and a relative increase for psychiatric reasons. I think a fair estimate at the present time of the relative ratio of indications for therapeutic abortion in American hospitals would be:

Maternal medical disease	10-40%
Psychiatric indications	30-50%
Fetal indications	20-40%

Fetal Indications

Fetal indications include (1) rubella, (2) Rh incompatibility, and (3) serious inherited defects, plus other teratogenic influences. By far the vast majority of therapeutic abortions in this country for fetal reasons are those for rubella. Time does not permit a review of the many pitfalls associated with this important problem. The lack of easily available virological diagnostic techniques is certainly one of the most urgent problems at present. You have been told that the risk of embryopathy during the first trimester is somewhere in the vicinity of 10-20 per cent, and since many of these defects are not really so bad anyway (though I daresay they would be considered so by most of society), there is no reason whatever to

justify the interruption of pregnancy for this cause. I have no quarrel with that conclusion in view of the facts that were presented, but I do feel strongly that a very important principle of teratology has been neglected, viz., the fact that the results of the action of any deleterious effect, be it a virus, radiation, anoxia, high temperature, or drug, can be evaluated only in relation to the stage of the developing embryo at the time the noxious agent was active. Inasmuch as the first trimester represents a time period during which the zygote undergoes almost complete organogenesis and becomes a completely formed organism differing only in maturation from the second and third trimester fetus, any risk figure expressed as a percent of embryopathy for the entire period really has no meaning when applied to a specific individual problem.

Rubella-Induced Embryopathy

Our discussion with regard to rubella-induced embryopathy should be limited to those studies that fulfill the following conditions:

1. There should be prospective studies.

Fig. 3

--- Sallomi, S. J.: *Obstet Gynec* 27:252, 1966.
— Rendle-Short, J.: *Lancet* 2:373, 1964.

*See page 119.

2. Rubella should have been established by an M.D.

3. The date of the last menstrual period and active disease should be accurately known.

4. Infants must have been examined by a physician.

5. Only anomalies typical of rubella should be included: cataract, microphthalmus, congenital heart, microcephaly, deafness, and mental deficiency. Minor anomalies and such things as anencephaly and hydrocephalus were excluded.

6. No therapeutic abortions should have been done.

Rendle-Short⁹ and Sallomi¹⁰ have reported such carefully chosen studies, and they show remarkable agreement. The total anomaly rate for live-born babies exposed to rubella in the first trimester was 14.9 per cent. However, if the anomaly rates are plotted by week of gestation against a logarithmic scale of percent of embryopathy, we get an entirely different impression of the risk rate for rubella. We see that at two to four weeks the risk is probably in excess of 60 per cent and falls to about 30 per cent at six to eight weeks and to around 10 per cent at 10 weeks (Figure 3). Actually, we should refine this and plot the risk in relation to days of growth from 14 to 100 days after the last menstrual period.

The obstetrical outlook for women exposed to rubella is actually poor when expressed in terms of expected full-term live birth of a normal child. In the case of exposure of one to eight weeks, the average expectancy of a normal child at birth is 35.8 per cent.¹⁰ These figures are probably minimal, since they do not include the newer findings of *bone, spleen, and hematological abnormalities*, nor do they take into consideration that almost every long-term follow-up of these cases has revealed more cases of *hearing defects and specific learning difficulties and mental retardation* as these children enter school. In view of these risks I feel strongly that insofar as we know them, the facts ought to be available to the patients to the degree they are able to under-

stand them and that prospective parents themselves have a right to share in the decision for or against therapeutic abortion.

Psychiatric Indications

In regard to the controversy over psychiatric indications for abortion,¹¹ I think the main difficulty has been a confusion of terms. It seems obvious to me that Doctors Bernstein and Teeter* are talking about two quite different concepts. The orthodox view of trying to decide on narrowly-defined psychiatric grounds whether a given patient will commit suicide, for example, or if her reactive depression will relent, is, in my opinion, lateral to the main problem and will lead us only to a numbers controversy. As a matter of fact, it has been, I think, amply demonstrated that pregnant women carry a lesser risk of suicide. Also in Scandinavia, only about 5 to 8 per cent of the therapeutic abortions are performed for reactive depressions per se.¹¹ The real issue is this: after careful investigation of an individual's total life situation — past, present, and predictable future — are her, and to a lesser extent her family's and society's welfare and happiness best served by having her continue with the pregnancy or by her having an early and therefore safe interruption of it? It is inconceivable to me to try to make such a decision without taking into account *all* of the manifold and interrelated considerations which may relate to the stress of a given pregnancy.

Comments

Are we to believe that we can properly evaluate the effects of the stress of a pregnancy on a patient's health and happiness as though she existed in a vacuum? Are we to ignore her own feelings about the child, her ability to care for the child when born, the number of other children and the effects of the pregnancy on them, the stability of the husband and the marriage itself, the economic factors, and many other considerations too numerous to list? Some of you will undoubtedly object to the idea that socioeconomic considerations have a place in a decision vis-à-vis therapeutic abortion. We have witnessed in our lifetime the evolution of the concept that we cannot separate

*See pages 49 and 51.

"psyche" from "soma," and I think we all now accept it. But I think it is time now that we take the next step and recognize that we cannot separate the patient and his treatment from the multiplicity of factors in his heredity, environment, past experiences, and present situation. To wait for perfection of social welfare goals or the improvement of the human condition is, it seems to me, simply an excuse to avoid facing up to a very complex and difficult problem. Science seems to have condemned us to live in a world of rapid social change, and we must realize that it is no longer possible to operate according to absolute rules. We must adjust to meet new conditions in a world that we know will not become perfect in the predictable future.

We can all agree that the essential obligation of a physician is the health and welfare of his patient. As Peabody of Harvard said many years ago, the secret of the care of the patient is in caring for the patient. The treatment of disease should be impersonal; the care of the patient must be completely personal. Fletcher¹² has defined personalism as "that doctrine that correlates personality and value and holds that personality is a unique quality in every human being, and that it is both the highest good and the chief medium of our knowledge of good." Under the orthodox psychiatric view interruption of pregnancy for psychiatric reasons may never be justified, but under a personalistic frame of reference, such a conclusion is manifestly unwarranted. That contradiction, it seems to me is the crux of the controversy. Difficult as it may be, I think we have no choice but *must* grapple with this problem at all levels and with the help from experts in all fields until we get at least part of the truth.

Legally proven rape and incest are included under psychiatric indications. More properly these cases should be included under humanitarian indications. Many psychiatrists who are normally opposed to abortion for psychiatric reasons favor abortion in these circumstances. My own belief is that it is completely uncivilized to force such patients to go through a pregnancy.

However, the law does not recognize these indications, and every therapeutic abortion done for these reasons is illegal.

We must be frank in admitting that underlying philosophic or religious assumptions are probably the most important factor in influencing how we interpret the facts regarding abortion. Therefore, if you believe that a soul is infused at the time of conception, obviously such a belief, which is beyond rational argument, is hardly consistent with approval of abortion for any reason. On the other hand, there are many who feel that a fetus is not a moral or personal being since it lacks freedom, self-determination, rationality, and any ability to choose either means or ends; that it also lacks knowledge of its circumstances and therefore cannot rationally react to them; that quite obviously it has no social relationships. It may be said to possess a potential life, and indeed this fact is recognized legally; but to equate such a life in all respects with a living person is in my view a wholly unwarranted twisting of reality to fit preconceived theological assumptions. For one group to accuse another group of committing murder under these circumstances is not only grossly wrong but, in addition, serves merely to further confuse and compound the problem. Such questions are best left to the field of religion. I do not by this suggestion mean to imply that we can separate morals (as distinct from religion) from scientific questions. On the contrary, science, and especially medicine, which deals so intimately with the happiness of individuals and the good of society, must be concerned with morals. I simply deny the *exclusive* right of organized religion to determine the morals of medical practice for us.

We all recognize that therapeutic abortion may not be a "good" solution to what is a very complex socioeconomic, medical-moral problem. It is, I am convinced, in our present imperfect world, a necessary alternative for some unfortunate human beings. But regardless of the merits of this argument, I do not feel we should retain an archaic law that is widely disregarded by both the public and the medical profession. Furthermore, be-

cause the loss of life and health from illegal abortion is a very serious public health problem, I would urge the society to go on record as favoring the changes in our abortion laws as recommended by the American Institute of Law, but I would emphasize that, by itself, changing the law will not solve the problem. We need to do much more than take that necessary step. I would suggest the following additional steps:

1. We should go on record as advocating consultation centers for women seeking abortion, where specialized, intimate, non-punitive guidance can be given. Such centers, if they served no other purpose than providing badly needed statistics and long-term follow-up information, would fill a real vacuum in our knowledge.

2. We should go on record as approving sex and family-life education in our schools

from the earliest grades through college, with emphasis on the moral and social responsibilities of parenthood.

3. We should reiterate that contraception is an essential part of good medical care and make it easily available to everyone who wants it.

4. We should support research into all phases of human reproduction.

5. We should actively lobby for a voluntary sterilization act so that responsible parents in the older age groups who wish to permanently free themselves from the threat of additional pregnancies may do so.

I am advocating these five measures in the firm belief that in spite of our very serious difficulties we all want to work toward the same goal: the maximum conservation of human life and happiness.

Medical Indications for Therapeutic Abortion

An
Obstetrician's
View*

DAVID G. DECKER, M.D.**
Rochester, Minnesota

NO OBSTETRICIAN wants to be labelled an abortionist. Yet all of us, on occasion, are called upon to perform an abortion at the request of our colleagues. At such a time we look for scientific and ethical guidelines to help us make the right decision. Many hospitals and clinics have created "abortion committees" to help shoulder the responsibility and, depending upon their composition and rules of conduct, these committees may be of great help to the individual obstetrician.¹ But in the final analysis no committee can actually perform an abortion. This must be done by the individual practitioner. Only when we, as individuals, are sure of real benefit to the pregnant woman can we bring ourselves to interrupt the pregnancy. The literature on the subject is confusing and contradictory. It is often highly emotional and far from scientific. Controlled experiments are, at least to the present time, impossible.

So, in the majority of instances, the final decision is reached on the basis of (1) religion, (2) medical ethics, (3) current practice, (4) sympathy for, or empathy with, the patient, and (5) medical evidence. Most of us, strongly conditioned by our Judeo-Christian inheritance, find something repulsive in the act of abortion.² So also, all of us are conditioned by previous medical experience and teaching and, with the years, generally become rigidly opposed to, or vehemently in favor of, therapeutic abortion as an indicated procedure.

A review of the foreign literature from countries where a liberal attitude prevails does not help to solve the dilemma.³⁻⁶ Again, confusing and diametrically opposed views concerning the abortion program may emanate from the same country.

*Part of the Symposium on Therapeutic Abortion read at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, April 23, 1966.

**Mayo Clinic and Mayo Foundation: Section of Obstetrics and Gynecology.

There are two questions involved: (1) are there any medical indications for therapeutic abortion; and (2) are there any psychiatric reasons for therapeutic abortion?

This discussion is directed to the first of these questions. Thirty years ago it was not so difficult to list medical indications for therapeutic abortion, but with rapid progress in the therapeutics of most diseases, it becomes increasingly difficult. For example, pulmonary tuberculosis, toxemia of pregnancy, hyperemesis gravidarum, hypertension, infectious nephropathy, thyrotoxicosis, diabetes mellitus, and acute rheumatic fever rarely appear as indications for abortion in series reported in the last 10 to 15 years.

In a review of the indications for therapeutic abortion at the Mayo Clinic in the past decade, certain broad categories have appeared as medical reasons for interrupting pregnancy.

Malignancy

Cervix

There is little question that treatment of an invasive carcinoma of the cervix results in the termination of pregnancy, and there is no argument at present regarding the necessity for that treatment—be it surgical or radiation therapy.

Pregnancy need not be interrupted for noninvasive carcinoma of the cervix when reasonable doubt about the diagnosis has been removed after conization.

Vulva

Pregnancy need not be interrupted as a part of the treatment of vulvar malignancy. Successful pregnancy can take place after radical surgery for this condition.

Carcinoma of the Breast

The indications for therapeutic abortion associated with carcinoma of the breast are tenuous. No statistical difference has been noted in the survival rate of patients who have aborted and those who have been allowed to proceed to term. The argument still rages as to whether nodal involvement should make the decision for abortion more definite.

The patient with an apparently estrogen-dependent breast cancer in whom metastatic lesions are being controlled by therapy should certainly be counselled against pregnancy and, if it occurs, may gain some months of life by having the pregnancy terminated. This would seem to be a relative indication for therapeutic abortion.

Also, the patient who has an inflammatory or rapidly progressing uncontrollable breast carcinoma would not seem a suitable candidate for pregnancy, but this is probably more a psychiatric than a medical indication for therapeutic abortion.

Malignancy of Bony Pelvis

Certain sarcomas of the bony pelvis that are treated by hind-quarter amputation may, in the pregnant patient, be treated more easily and with better healing if the pregnancy is terminated.

Carcinoma of the Rectum or Sigmoid

Primary treatment of malignancy in this region may result in the loss of the pregnancy but, depending on the location, this is not inevitable. The survival rate is affected by the pregnancy per se only when pregnancy interferes with adequate therapy.

Brain Tumors

Certain brain tumors become markedly edematous in association with pregnancy, and symptoms may increase out of proportion to the disease present. Also, vascularity is increased and surgery becomes more difficult technically. Therefore, in certain cases therapeutic abortion may be requested by the neurosurgeon and, in early pregnancy, probably should receive careful consideration.

Renal Disease

Chronic Renal Insufficiency

Such a condition, from whatever cause, may be a reason for therapeutic abortion. This is especially true where renal failure ensues and the patient is being maintained on the artificial kidney. The patient who is being considered for renal transplant usually will not become pregnant, but we are

now being faced with the post-transplant patient who should not become pregnant for six months to one year afterward. Prevention is obviously the better approach, but should pregnancy occur, consideration of interruption should be given.

Resistant Infection in Kidney

Rarely does resistant infection become severe enough in modern medical practice to indicate therapeutic abortion, but the rare instance, particularly with a solitary kidney, may arise when the urologist believes that the pregnancy is adversely affecting the control of the process.

Toxemia of Pregnancy

It is almost unheard of to consider abortion for toxemia, but in the rare case of early midtrimester fulminating toxemia with renal shutdown, interruption of the pregnancy may be lifesaving for the mother.

Cardiovascular Disease

Cardiac Surgery

The increasing scope of cardiac surgery has completely altered the indications for therapeutic abortion in congenital or acquired heart disease. At the present time no cardiac surgeon hesitates to operate on the pregnant patient. The only reluctance evidenced by cardiac surgeons at our institution was in a case in which the implantation of artificial valves required prolonged and intensive anticoagulation therapy.

Hypertension

With present modes of therapy, hypertension is rarely uncontrollable. Occasionally, however, severe pulmonary hypertension may still raise the question of therapeutic abortion.

Aneurysm

Surgical replacement of aneurysmal dilations is not a contraindication to pregnancy. Cerebral aneurysm with rupture may be a cause of acute episodes, but usually such patients are not particularly benefited by interruption of a pregnancy.

Diabetes Mellitus

Diabetic Nephropathy

The patient with severe diabetic nephropathy may be considered a candidate for interruption of pregnancy, but such nephropathy is no longer an absolute indication.

Diabetic Retinopathy

Severe diabetic retinopathy may be adversely affected by pregnancy and, particularly in those patients in whom pituitary-stalk section is contemplated, interruption of pregnancy may be requested.

Neurologic Disease

Rarely, a neurologic disease such as severe multiple sclerosis or myasthenia gravis may so compromise the health of the pregnant woman that the additional strain of pregnancy may seem unjustifiable to the neurologist. Again, this is a relative indication for abortion, and many factors must be balanced before a decision is reached.

Fetal Indications

Rubella

The reports on the incidence of congenital anomalies after rubella in the first six weeks of pregnancy are very confusing. Varied incidences of anomalies associated with the type of epidemic and the difficulty of diagnosis involved are evident. At present, wholesale therapeutic abortion for this condition does not seem valid.

Erythroblastosis Fetalis

The indications for abortion for this condition have been and are being altered by the techniques of exchange transfusion and more recently of intrauterine transfusion.

Inheritable Disease

At the present time, the problems of this broad group of conditions preclude any firm advice to the pregnant woman in most instances.

Conclusions

This list of conditions is not intended to be all-inclusive but rather is intended to indicate that there are few, if any, absolute

medical indications for therapeutic abortion in the present state of medicine. Almost all of the indications are relative. Of even more significance is the fact that each situation must be evaluated on its own merits. No blanket regulations are possible.

The obstetrician cannot lose sight of the fact that he is not only treating a patient in an immediate condition, but by performing a therapeutic abortion he may produce long-range effects that are both physical and mental. Therapeutic abortion is not an innocuous procedure. Chronic pelvic infections can be produced. Infertility or sterility may follow and, under the best controlled conditions, death may occur. Compounding the risk is not justifiable, and repeated abortion signifies failure of the obstetrician to control the situation. Where

therapeutic abortion is performed because of a chronic medical situation, sterilization should be done at the same time.

Recent studies from Denmark⁶ seem to emphasize that delayed guilt reactions may be a real problem and that some immediate psychiatric conditions may also be present. Improving the legal interpretation of therapeutic abortion is different from broadening the base for the procedure. Certainly that base, at least for medical indications, seems to be narrowing steadily.

In the final analysis, the obstetrician must make the ultimate decision whether or not to do a therapeutic abortion. He may be aided by consultation with his colleagues in various specialty fields and by the approval of his legal advisers; but in the operating room he stands alone.

Oliver Wendel Holmes, M.D. To the Young Practitioner

We had a physician in our city whose smile was commonly reckoned as being worth five thousand dollars a year to him, in the days, too, of moderate incomes. You cannot put on such a smile as that any more than you can get sunshine without sun; there was a tranquil and kindly nature under it that irradiated the pleasant face it made one happier to meet on his daily rounds. But you can cultivate the disposition, and it will work its way through to the surface, — nay, more, — you can try to wear a quiet and encouraging look, and it will react on your disposition and make you like what you seem to be, or at least bring you nearer to its own likeness.

Male and Female

An opportunist is a man who, finding himself in hot water, decides that he needs a bath anyway.

An opportunist is a woman who finds the wolf at the door and appears later in a new fur coat.

— Watchman-Examiner

Democracy is liberty plus economic security. We Americans want to pray, think as we please — and eat regular. — Maury Maverick

The Importance of Corn Allergy

KENNETH J. JOHNSON, M.D., M.S., F.A.C.A.*
Bismarck, North Dakota

WITH FEW EXCEPTIONS in the literature corn allergy has been minimized as shown by the following quotations. Hill¹: "Any food can cause asthma but not many foods commonly do so. Fish, egg, walnut, peanut, chocolate, are the most important." Unger²: "The only major foods which are frequent causes of migraine are chocolate, milk, wheat and pork." Carpenter³: "Foods are more likely to produce cerebral reactions than inhalants are. Thus, foods should be considered first. Milk, wheat, egg, chocolate, nuts, pork, and coffee are perhaps the most important." Withers and Hale⁴: "Although there is a difference of opinion regarding which foods most frequently cause symptoms [in food allergy], it is generally agreed that the foods used most often in the diet are usually the most common offenders. These are the basic ones, such as wheat, egg, milk, potato, beans, tomato, and chocolate." Davison⁵: "The ten most common foods incriminated [in cerebral allergy], in order of frequency, were: milk, chocolate, onion, cabbage, pork, eggs, fish and shellfish, tomatoes, nuts, and apples." Halpin⁶: "Since corn starch is practically free of protein, allergic reactions to its ingestion have been rare." Prickman⁷ and Coca⁸ found corn to be the least common. In a poll⁹ of allergists clinical symptoms from ingested corn were encountered in only 0.16% of 45,000 patients. This is in marked contrast to 16-30% of Rinkel, Randolph and others. Randolph¹⁰ found allergy to corn was present in 87, wheat in 85, milk in 75, and eggs in 67. The high incidence of corn sensitivity shown by these data makes it imperative that corn allergy be considered in all cases suspected of food sensitivity. Criepp¹¹ seems to agree with Randolph. Conrad¹² wrote an excellent guide on cooking in respect to milk, wheat, and eggs, but neglects corn. She recognizes that "corn syrup and corn sugars

*Allergist, Quain & Ramstad Clinic, Bismarck, North Dakota.

frequently cause trouble"; but in her "basic diet" (to avoid food allergens) she includes and allows the following foods, all of which may contain corn¹⁴: canned salmon, pork, bacon, ham, French dressing, potato chips. Brown and Brown¹³ in a discussion of gastrointestinal symptoms of food allergy include a case report of one patient who was skin-test sensitive to corn as well as to eleven other foods.

This conflict as to the importance of corn is probably due to (1) corn's ubiquity, the patient and the physician usually being unable to recognize corn when it is present (corn is found in over 130 everyday foods¹⁴); and (2) the lack of an adequate reliable diagnostic test for food allergy until the development of the provocative intradermal food test.¹⁵

In an attempt to resolve the contradictions in the literature regarding the importance of corn allergy, fifty consecutive patients were compared who reacted positively to one or more foods by the provocative intradermal food test. Of these fifty patients 38 were female and 12 male. Twenty females and five males gave a positive reaction to corn.

Symptoms of Corn Allergy

Numerous symptoms were elicited by these tests. Each symptom usually occurred in only one or two patients. This suggests that symptoms are hard to describe and are probably similar in several patients, each, however, expressing them differently.

The following symptoms which I interpreted as probably due to increased mucin production were described by various patients: throat feeling thicker, something in throat, formation of phlegm in throat, need of clearing throat, sinus drainage in throat, postnasal drip, runny nose, stuffy nose and throat, dry throat, dry mouth and nose, cough, frothy saliva.

Increased Capillary Permeability

These symptoms, interpreted as caused by increased capillary permeability, may well have been almost identical: full feeling in the upper chest, pressure in the chest similar to when patient had severe hives, stuffy chest, pressure in the middle of the head,

feeling of density in the head, feeling of exhilaration in the head, light-headedness, dizziness, bitemporal headache, frontal headache, occipital headache, retro-orbital headache, numbness of the throat and back of the head, tiredness, weakness, drowsiness, sleepiness, sweating, warm flush, eyes feeling puffed, burning eyes, trouble focusing, itching eye, itchiness all over, itchy face, roof of mouth itching, itchy throat, itchy nose, sneeze.

It is not clear whether any symptoms should be ascribed to smooth muscle contraction. Burping, which was noted in more than one patient, may not have been an allergic reaction. Most symptoms are ascribed to increased capillary permeability. Those few ascribed to increased mucin production may be secondary to increased capillary permeability.

The positive findings in the provocative intradermal food test in these 25 patients were confirmed by having them avoid corn in all its forms and note an alleviation of their symptoms, then having them deliberately eat corn in some form and note a recurrence of their symptoms. Various patients noted symptoms from various forms of corn in their food. The usual story was that they were able to associate their symptoms with all the forms of corn in their food only after studying a list of 130-odd foods which are known to contain corn.¹⁴ *In the illustrative case reports which follow, the foods containing corn are italicized for easier recognition.*

Case Reports

Case One

This 32-year-old woman had had wheezing and a stuffy nose since age 12, which required hospitalization for her asthma every year at odd times. She had noted that *ham* and *peanuts* caused wheezing. She had been avoiding eggs and milk because her local physician had found that these foods gave a positive skin test; nevertheless, avoiding milk and eggs had not helped her asthma. She had received some benefit from house-dust allergen injections. For several months she had had constipation followed by diarrhea, and spasms or cramps in her abdomen; proctoscopy and colon X rays were negative.

In eliciting details of her history, it was found that she often woke up at night with itchy, sandy eyes and swollen lids; during the day she gained five to seven pounds, with much burping and bloat-

ing, and in the evening abdominal distention forced her to loosen her clothing. These symptoms worsened about 45 minutes after her larger meals; often she would become very sleepy after meals, so that she was afraid to drive a car because of several near accidents due to dozing for a moment while driving.

She disliked bread but preferred dark to white bread (which is made from *bleached flour*). Her favorite foods were lettuce, *catsup* and *saucers made from catsup*, beef, liver, fish, and *corn*. *Corn* was the main vegetable in her home. Lettuce was eaten at almost every meal, sometimes even as a main dish such as a lettuce sandwich. She often craved lettuce, and usually put *salad dressing* or *mayonnaise* on it. Beans of any kind made her lips swell. She bloated from eating *popcorn* or *corn on the cob* or from drinking *beer*. Her favorite drink was *sloe gin sour*. She had found that *ham* or *peanuts* caused wheezing, and apples caused cramps in her abdomen. Her daily foods were *catsup*, *corn*, *corn flakes*, macaroni, potatoes, peas, lettuce, onions, Sanka, *corn meal*, *gelatin*, and beef. She had eaten a lettuce sandwich for supper the day before her office visit and recalled she could hardly stay awake after supper.

Provocative intradermal food test showed a positive reaction with corn (belching, formation of phlegm in her throat, and cough); with potato (sensation of swelling of the roof of her mouth and belching); and with lettuce (belching, yawning, and sleepiness). Egg and milk gave negative reactions.

After being on a corn-free diet she had no more bloating or erratic bowel habits; her asthma had improved tremendously, and she no longer gained several pounds of weight during the course of each day. The sandiness and itching of the eyes and the swelling of the eyelids also cleared, and she felt much

better in general. She broke her diet once by eating popcorn one evening and bloated so much that she had to change her clothes to accommodate the increase in girth, as had happened so often before going on her corn-free diet.

Case Two

Since early childhood this 14-year-old boy had had a chronic cough diagnosed repeatedly as bronchitis; once his chest X ray had shown pneumonia. For a long time he had also had a stuffy, runny nose, present year round, and worse at night when he lay down or when he was active or out in cold weather. Further complaints elicited on questioning were chronic tiredness, drowsiness after some meals, and enuresis until age 12. He had noted that eating *ice cream* gave him a headache, and *milk* "stuck to his throat" and tasted sour. His favorite foods were sour cream, hamburger, chicken, spaghetti, *cinnamon rolls*, *creamed corn*, *corn on the cob*, *corn bread*, *pies*, and *cookies*. He disliked liver, peas, boiled potatoes, chicken heart, baked beans, *milk*, *corn flakes*, *peanut butter*. The milk he drank came in *paper cartons*. The evening before testing for foods he had eaten hamburger sandwiches, *catsup*, and *corn chips*. His cough was worse that night. His lunch that day had consisted of *vegetable soup* and sandwiches of *peanut butter*, *tuna*, and butter. That afternoon he had felt very drowsy.

A swab of the material from the floor of his nasal cavity when stained revealed many eosinophils. Intradermal skin tests proved him to be sensitive to house dust. A provocative intradermal food test showed negative findings with wheat, but corn testing elicited the symptoms of drowsiness, definitely increased stuffiness of nose and throat, cough, itchy throat, and burping. These were cleared by a neu-

TABLE I

Corn product:	Equivalent corn-free product:
Bakery bread (made from bleached flour)	Frozen bread dough (made from unbleached flour)
Beer, whiskey, ale, cola	Rum, brandy, wine, vodka
Candy	Hershey's chocolate
Carbonated beverages	Cocoa, apple cider, Diet Pepsi-Cola
Catsup (commercial)	Homemade catsup
Cooking oil (e.g., Mazola)	Cottonseed oil, lard, olive oil, safflower oil
Corn flakes	Shredded wheat
Bleached flour	Rice flour, wholewheat cracked flour, rye flour, graham flour
Canned fruits, frozen fruits, fruit juices	Fresh fruits, water-packed fruits, unsweetened canned goods
Graham crackers	Rye-Krisp
Grape juice	Welch's grape juice
Gravy	Beef juice, butter
Ice cream	Dietetic ice cream
Commercial jams and jellies	Homemade preserves
Sausage, bologna, wieners	Fresh meats
Milk in paper cartons	Milk in glass bottles
Ready-to-bake mixes	Natural foods, raw foods home-cooked
Oleomargarine (from corn oil)	Butter, cottonseed oil oleomargarine, safflower oil oleomargarine
Peanut butter	Honey
Oil-packed salmon	Water-packed salmon
Restaurant salt	Pure salt
Powdered sugar	Crystal sugar
Syrup	Honey
Oil-packed tuna	Water-packed tuna
Canned vegetables sweetened	Unsweetened or water-packed canned vegetables
Distilled vinegar	Apple cider vinegar
Kosher foods	Passover foods

tralizing dose of corn. The test for milk produced a stuffy, sticky, sore sensation in the throat, which also cleared by injection of a neutralizing dose.

On desensitizing house dust injections and on a milk and corn-free diet he has become relatively asymptomatic for the first time in his memory.

Comments

Since thyroid insufficiency often occurs in allergy patients a survey was made in 1965 of the 100 pharmaceutical companies listed by the Red Book as manufacturers of thyroid tablets to see which brands did not contain corn, so that the allergy patient for whom thyroid was prescribed would not be receiving corn starch in his tablets. Of the 61 companies answering my letter of inquiry, only 16 did not use corn. The base or filler or binder used by these companies appeared to be lactose, talc, wood cellulose, mineral oil, cane or beet sugar, acacia, and/or potato starch. The most widely known of these 16 firms are Burroughs Wellcome & Co., Hynson, Westcott & Dunning, Wm. S. Merrell Co., and Warner-Chilcott Laboratories.

Other medications are also prone to contain corn. For the corn-allergy patient the safest procedure appears to be prescribing liquid medications other than syrups and the giving of injectables instead of oral medications where feasible.

Avoiding corn in the diet when there are about 130 foods containing corn and other corn contacts¹⁴ (including corn starch, corn syrup and corn oil) is a formidable task. The less determined patients and the less intelligent fail. Only one of my patients claimed she had no difficulty following the corn-free diet; she lived on a ranch where they did their own butchering, raised their own vegetables, did their own cooking and baking and canning, and "never" bought groceries in a store.

In order to give the corn-allergy patient advice more positive than a long list of foods to be avoided, a list of equivalents was prepared. Of course this list is not infallible and no list can be permanent, since

ingredients of commercial foods are always subject to change (See Table 1).

It has been theorized that since the neutralizing dose of food allergen removes the symptoms induced by the provocative dose in the provocative intradermal food test, then that same dosage and dilution should remove the symptoms caused by ingestion of that food. In my experience that is true. Selected patients have been given a bottle containing the neutralizing dilution of those foods to which they were allergic and disposable syringes and needles with instruction how to give themselves the neutralizing dosages as needed. In the dozens and hundreds of times these injections have been given the procedure has been almost 100% successful, according to the testimony of the patients.

Conclusion

1. Of 50 consecutive patients who had food allergies, 25 were allergic to corn, as demonstrated by the provocative intradermal food test and confirmed by a careful detailed history and by diet trials. Accordingly, corn should be considered one of the most important causes of food allergy.

2. In these patients there was a four to one preponderance of females.

3. Most drugs in tablet or capsule form are apt to contain corn.

4. Since corn is found in so many foods and is not easily detected in them, a list of corn-free foods should be given to the patient so that substitutions may be made. Such a list is presented.

5. A bottle containing the neutralizing dilution of corn and other allergenic foods may be given to the patient, who may self-administer the injection when the diet is broken and allergy symptoms result. In my experience this has been almost 100% successful in relieving allergy symptoms, according to the testimony of the patients themselves.

Cerebral Blood Flow and Metabolism

During Experimental Hyperthermia (Fever)

JOHN S. MEYER, M.D.*
Detroit, Michigan
JYOJI HANDA, M.D.*
Kyoto, Japan

IT IS COMMON knowledge that high fever from any cause may be associated with delirium, stupor, coma and occasionally irreversible neurological deficit such as cerebellar ataxia. The neurologic and electroencephalographic disorders that result may be due to effects of hyperthermia on the enzymes or membranes of nerve cells, or on both. In children and occasionally adults, hemiplegia due to vascular occlusion may be precipitated by fever. The explanation for this has never been clarified. Possibly changes in clotting properties of the blood may occur, but if fever results in increased cerebral metabolism and blood flow, then regional neurological deficit may be expected to result in areas of diminished perfusion due to congenital anomaly or disease of cerebral vessels.

There are few observations of the electroencephalogram, cerebral circulation, and metabolism during hyperthermia; and those that are available do not agree. In order to clarify these problems, the following experiment was devised:

Changes in the electroencephalogram, cerebral blood flow, and oxidative metabolism were correlated during experimental hyperthermia in suitably anesthetized and immobilized monkeys and cats.

Method

Preparation of the Animals for Surgery

Sixteen *Macacus rhesus* monkeys of both sexes weighing 3 to 4 kg. and ten cats were used. Surgical anesthesia was induced by ether inhalation with atropine sulfate (0.2 mg/kg.) injected intravenously. The femoral artery and vein were cannulated and tracheostomy was performed. After surgery was completed, the incision sites were carefully anesthetized using 0.5% lidocaine hy-

This study was supported by grants from the United States Public Health Service and the Detroit General Hospital Research Corporation.

drochloride (Xylocaine®). Immobilization was achieved by intravenous injection of 20 mg. of gallamine triethiodide (Flaxedil®), and respiration was maintained with a Harvard Respirator. The maximum total dosage of gallamine was 40 to 60 mg.

Operative Exposure

Through a midcervical incision from the hyoid bone to the suprasternal notch, both carotid arteries and both internal jugular

*Model M-4001, Medicon Division of Statham Instruments, Inc., Los Angeles, California.

Fig. 1 — Summary of results of fever in the monkey. To show changes in cerebral venous flow, cerebral vascular resistance, mean arterial blood pressure, cerebral metabolic rate for oxygen, expired carbon dioxide from the trachea, and cardiac rate during induced hyperthermia in the monkey.

veins were exposed. When outflow from both internal jugular veins was measured (10 monkeys), the external jugular, vertebral and common facial veins and other tributaries of the internal jugular veins were ligated.¹ It has been shown that jugular venous outflow measured in this manner correlates in a statistically significant manner with cerebral blood flow measured by the nitrous oxide method.²

In the remaining six monkeys the internal carotid, external carotid, and vertebral flow were measured in various combinations. In three monkeys in which measurements of vertebral flow were performed, the left vertebral artery was exposed from its origin to the entrance into the foramen transversarium and the flow-probe was applied. The lower portion of the brachial plexus and the left stellate ganglion were sectioned to permit adequate exposure of the vertebral artery. The carotid sinuses were not denervated.

Determination of Blood Flow

Continuous determinations of blood flow were made with two Microflo sine-wave flowmeters* or one Microflo and one Metreflo square-wave flowmeters.

Because of technical difficulties in placing the flowmeter probe directly on the internal or external carotid artery, the remaining blood flow through the common carotid artery after ligation of the external carotid was named "internal carotid flow," and the remaining flow, after occlusion of the external carotid, was called "external carotid flow." It has been shown previously that this assumption is justified provided that the blood pressure does not fall to shock levels.³ In order to examine any possible differences between external and internal carotid flow, the flows were measured simultaneously in two animals, and the above assumption was found to be correct in the present preparation.

Induced Hyperthermia

Hyperthermia was induced by a warming pad irrigated with hot water. The rate of warming varied in each animal, but in most

of the studies the rectal temperature was raised from normothermic levels to 40-41.0° C. in two hours. Blood pressure was recorded with a Statham strain-gauge from a catheter threaded into the abdominal aorta via the femoral artery. Carbon dioxide concentration of the expired air was monitored with a Beckman Medical Gas Analyzer (Spinco Model LB-1). Recordings of blood pressure, blood flow and endotracheal carbon dioxide concentration were made by a Grass Model V Polygraph. Electroencephalogram and electrocardiogram were recorded with a Grass Model III-D Electroencephalograph. Rectal temperature was measured with a thermometer accurate to 0.1° C.

In the monkeys periodic samples of arterial and cerebral venous blood were drawn from the femoral artery and the internal jugular vein, and oxygen content was determined by the gasometric method of Van Slyke. In 10 cats, changes in the electroencephalogram and electrocardiogram, blood pressure and endotracheal carbon dioxide concentration were compared to observations in the monkey. In three cats, femoral artery flow was measured during hyperthermia. Since the changes in the parameters measured in the cat were the same as in the monkey, the results in the monkey will be described, and only those observations in the cats which are considered pertinent will be mentioned.

Results

The results of the experiments in the monkeys are summarized in Figure 1.

Arterial Pressure

Mean arterial pressure was calculated by adding one third of the pulse pressure to the diastolic pressure. In all monkeys mean arterial pressure was relatively high, varying from 87 to 145 mm. Hg., the average being 114 mm. Hg. (Standard deviation = ± 22.4) in the steady state. Changes in mean arterial pressure during hyperthermia are summarized in Figure 1.

In three monkeys hyperthermia was maintained around 41° C. In two of the remaining 13 monkeys in which hyperthermia was prolonged, mean arterial pressure remained

essentially unchanged until a rectal temperature of 41.5-42.4° C. was reached, when shock developed rapidly. In another two monkeys blood pressure decreased slightly but progressively, and at 41.5-42.9° C. circulatory collapse occurred. In eight monkeys mean arterial pressure first showed an increase, reaching a maximum at 41.5-42.9° C., blood pressure thereafter decreasing. In one experiment the blood pressure fell below 30 mm. Hg. when the temperature was only 40° C.

In mean arithmetic terms, mean arterial pressure increased gradually from 11 mm. Hg. (Standard deviation = ± 22.4) in the steady state to 138 mm. Hg. (Standard deviation = ± 18.9) at 41.5-41.9° C. (106.7-107.4° F.) and then failed rapidly (Figure 1).

Carbon Dioxide Content

Carbon dioxide content of the expired air

Fig. 2 — Summary of results of hyperthermia on blood flow through the major cephalic arteries in the monkey. To show changes in external carotid flow (ECF), internal carotid flow (ICF), and vertebral flow (VF) during hyperthermia in the monkey. Cerebral venous flow (CVF) also is shown for comparison.

increased steadily in all 16 monkeys except one in which the carbon dioxide content decreased briefly before the increase (Figure 1). Maximal values were obtained at 41.5-42.2° C. in nine of the 15 monkeys; thereafter the carbon dioxide content decreased. On the average, carbon dioxide increased from resting values of 2.0% (Standard deviation = ± 0.3) to a maximum of 2.8% (Standard deviation = ± 0.5) at 41.5-42.4° C. (106.7-108.3° F.).

In connection with the steady increase in tracheal carbon dioxide during hyperthermia, it should be pointed out that the animals were ventilated artificially at constant frequency and volume, so that the tachypnea usually seen in hyperthermia was prevented.

Heart Rate

Cardiac rate increased without exception. In eight of 13 animals in which hyperthermia was continued until shock, cardiac rate reached a maximum at 41.5-42.9° C. When average values were calculated for the group, the cardiac rate increased from 212 (Standard deviation = ± 28) in the steady state to 276 (Standard deviation = ± 03) at 42.0-42.4° C. (107.6-108.3° F.); thereafter it decreased.

Cerebral Blood Flow

Bilateral internal jugular venous flow was measured simultaneously in 10 monkeys; in seven of these, hyperthermia was continued until shock occurred, and in three a temperature of 41.0° C. (105.8° F.) was maintained for 60-80 minutes. In this series of 10 monkeys, cerebral blood flow, estimated in terms of cerebral venous outflow, ranged from 47.0 to 67.0 cc/100 g/Brain/min. in the steady state with a mean value of 57.7 cc. (Standard deviation = ± 6.5) at body temperature of 37.0° C. ± 0.9 .

During induction of hyperthermia, cerebral blood flow remained unchanged until body temperature reached 39.0-39.4° C. (102.2-102.9° F.). At this temperature mean cerebral venous outflow was 60.0 cc/100 g/Brain/min. (Standard deviation = ± 5.5 p > 0.1) when compared to the steady state (Figure 1). Above 39.4° C. cerebral venous

outflow increased steadily to reach maximal values of 86.0 cc/100 g/Brain/min. at 41.5-41.9° C. (106.7-107.4° F.) (p < 0.001). Above 41.9° C. cerebral venous outflow decreased rapidly.

Vascular Resistance

Cerebral Vascular Resistance ranged in the steady state from 1.7 to 2.6 mm. Hg/cc/100 g/Brain/min. for the seven monkeys in which warming was continued until shock developed, the average being 2.2 (Standard deviation = ± 0.4) at a temperature of 37.0° C. ± 0.9 . During induction of hyperthermia, cerebral venous outflow remained stable until 39.5-39.9° C. (103.1-103.8° F.); then it progressively decreased (Figure 1). The mean values at 39.5-39.9° C. and 40.0-40.4° C. were 2.0 (Standard deviation = ± 0.4) and 1.9 (Standard deviation = ± 0.5) respectively; but the decrease from the resting level of 2.2 was not statistically significant for either. At a temperature of 40.5-40.9° C. (104.9-105.6° F.) the decrease of cerebral vascular resistance to 1.8 (Standard deviation = ± 0.4) reached the level of statistical significance (p < 0.05).

Cerebral Metabolic Rate of Oxygen

This increased significantly during induction of hyperthermia. The control values for cerebral metabolic rate of oxygen in the steady state (36.3-38.1° C.) ranged from 2.0 to 4.4 cc/100 g/Brain/min., the average being 3.4 (Standard deviation = ± 0.8). During hyperthermia at body temperature of 40.0-42.0° C. cerebral metabolic rate for oxygen increased to 4.1-5.0 cc/100 g/Brain/min. with a mean of 4.6 (Standard deviation = ± 0.3). This increase of cerebral metabolic rate of oxygen from 3.4 to 4.6 (ca. 35% increase) was statistically significant (Figure 1). When body temperature exceeded 42° C. (107.6° F.), cerebral metabolic rate of oxygen rapidly decreased.

Regional Cephalic Blood Flow During Hyperthermia

Since quantitative blood flow through the internal carotid, external carotid, and vertebral arteries varied in the steady state in

different animals, measurements during hyperthermia were expressed as percentages of resting values (Figure 2). Values for internal jugular venous outflow are correlated for comparison.

Internal Carotid

General patterns to flow change in the internal carotid and vertebral arteries compared well with those in the internal jugular veins. In three out of four monkeys in which the *internal carotid flow* was measured, flow increases of 37-47% occurred during hyperthermia at 41-42.5° C. In one animal internal carotid flow did not increase during the course of experiment nor did any pressor response occur. At 42° C. the blood pressure and internal carotid flow decreased rapidly.

Vertebral Artery

Vertebral artery flow was measured in three monkeys, maximal increases being 31-50% at 40-43° C. Simultaneous flow measurements of both internal carotid and vertebral arteries in one monkey showed identical changes.

External Carotid

External carotid flow showed fluctuations related to those of blood pressure. At the beginning of the study external carotid flow and blood pressure records were a mirror image, i.e., sharp increases in blood pressure were accompanied by decreases in external carotid flow. During hyperthermia, this pattern was reversed, i.e., during sharp increases of blood pressure increases in flow followed.

Detailed mechanisms of this phenomenon are out of the scope of the present paper. However, it might be assumed that in the beginning, periodic vasoconstriction and the resultant increase in peripheral resistance are the main factors for paroxysmal increase in the blood pressure. When the body temperature was raised further and the peripheral vessels were dilated, any increase in the blood pressure, presumably of cardiac origin, produced passive distention of the peripheral vessels by higher pressure head, thus passively increasing the blood flow.

When there was any significant paroxys-

mal fluctuation of the blood pressure and blood flow, readings of the blood flow were taken at the lowest blood pressure levels. In all five studies where external carotid flow was measured there was an increase soon after hyperthermia was induced at a time when the internal carotid and vertebral flow still remained unchanged. The increase in external carotid flow was much greater than the increases of the internal carotid, vertebral, or internal jugular flow, maximal values appearing at 40-42° C. with a 100-160% increase. In one monkey flow measurements were not made beyond 38.6° C. because of technical problems with the flowmeter (Figure 2).

In three *cats* blood flow through the femoral artery was measured during hyperthermia. Femoral arterial flow, like external carotid flow, also started to increase after the onset of warming and rose to 360% of the steady state at 39.7-42.50 C.

In brief, internal carotid, vertebral artery, and internal jugular flow all showed maximum increases of 25 to 50% with one excep-

Fig. 3 — Summary of effects of sustained hyperthermia. To show the effects of sustained hyperthermia on mean arterial blood pressure, cerebral venous outflow, cerebral vascular resistance, and cerebral metabolic rate for oxygen in the monkey.

tion. Peripheral arterial flow, including the external carotid flow, increased at an earlier stage than cerebral blood flow, and maximum increases were greater.

Effects of Prolonged Hyperthermia

In three monkeys the temperature was maintained around 41.0° C. (105.8° F.) for 60-80 minutes; the results are summarized in Figure 3. In one monkey the temperature increased by 0.4° C. after warming was discontinued, then decreased to 41.0° C. approximately 40 minutes later. During this interval of 40 minutes, mean arterial pressure decreased from 120 mm. Hg. to 62 mm. Hg. Cerebral venous outflow increased from 65 cc/100 g/Brain/min. in the steady state to 77 cc. at 41.0° C.; but when the temperature decreased to 41.0° C. again, cerebral venous outflow fell to 58 cc., below the resting level. Cerebral vascular resistance progressively decreased during the 40-minute interval from 1.5 to 1.0 unit, and cerebral metabolic rate for oxygen decreased from 217 to 2.1 cc/100 g/Brain/min.

A similar progressive decrease in mean ar-

terial pressure, cerebral venous outflow, and cerebral vascular resistance was likewise observed during sustained hyperthermia in one monkey; in another the mean arterial pressure remained stable, but cerebral venous outflow and cerebral metabolic rate for oxygen decreased.

Electroencephalographic Changes During Hyperthermia

Unipolar and bipolar electroencephalograms were recorded in all animals except one cat. Except for periodic changes accompanied by paroxysmal elevations of blood pressure, the electroencephalogram remained normal until the temperature reached 41.0-42.0° C. (105.8-107.6° F.). When these temperature levels were exceeded, sporadic bursts of slow waves appeared in the theta range. In 12 monkeys the temperature was raised further and sporadic delta waves appeared at 42.0-43.4° C. (107.6-110.1° F.). Between 43.0-44.0° C. (109.4-111.2° F.) diffuse delta activity appeared, and the record became flat between 43.5-46.0° C. (110.3-114.8° F.).

In every case where correlation was possible, the increase of theta and appearance of delta waves coincided with the rapid decrease in cerebral blood flow (either jugular outflow or arterial inflow) from maximal to subnormal levels. In one monkey the electroencephalogram slowing appeared at the relatively low temperature of 39.5° C. and became flat at 40° C. This monkey's cerebral venous outflow also decreased prematurely at 39.8-39.9° C. along with the appearance of delta waves in the electroencephalogram.

During sustained hyperthermia at 41° C. the electroencephalogram showed progressive slowing despite a stable temperature of around 41° C.; this was also accompanied by a progressive decrease in cerebral blood flow and metabolism (Figure 4B). Seizure activity in the electroencephalogram was observed in three of 11 cats between 42-45.8° C.; but spike activity was not observed in the monkeys.

Discussion

Although hyperthermia is known to cause

Fig. 4 — To show progressive electroencephalographic changes during induced hyperthermia in the monkey.

significant changes in circulation and metabolism of the body as a whole as well as of several organs,³ few measurements have been made of the effects of fever on cerebral blood flow and metabolism, and these few are not in agreement.

Increased Cerebral Oxygen Consumption during Fever

In-vitro studies of the rat brain showed increased oxygen consumption as the temperature reached 40° C. At 37.5° C. or below, QO_2 was constant for more than three hours; however, at 40° C. and above, QO_2 diminished the longer the temperature was sustained.⁴ Himwich et al.,^{5,6} using rat brain, noted increased cerebral oxygen uptake with increasing temperature between 25° C.-44° C. Above 44° C. the increase in oxygen uptake ceased. They also showed that above 40° C. sustained hyperthermia for 50 to 60 minutes resulted in a rapid reduction of oxygen uptake when compared with measurement at 20 minutes.

Despite the above results Dixon⁷ reported that the oxygen uptake of rabbit brain was only slightly higher at 42° C. than at 37° C.; at 45° C., however, oxygen uptake was increased by 100%.

Arteriovenous Oxygen Difference

Cerebral arteriovenous oxygen differences in man were reported to be increased by more than 2.0 vol. % during fever therapy. This was found in 11 of 15 subjects treated for general paresis, using typhoid vaccine, malaria, or external heat.^{8,10} It was concluded that during hyperthermia in man, either cerebral metabolism increased to a greater degree than in other parts of the body or cerebral blood flow decreased. Contrary to these findings, Looney and Borkovic⁹ reported essentially no change in cerebral arteriovenous oxygen differences in 12 paretic patients treated with diathermy.

Cerebral Blood Flow and Metabolism

To our knowledge the only measurements of cerebral blood flow and metabolism in man during fever therapy were reported by Heyman et al.⁸ They measured cerebral blood

flow and oxygen consumption by the nitrous oxide method during fever induced by typhoid pyrogen or malaria. In 13 patients with asymptomatic neurosyphilis, cerebral blood flow and cerebral metabolic rate for oxygen were normal in the afebrile state and showed minimum changes during fever up to 101-104° F. (38.3-40.0° C.). Fourteen subjects with paretic neurosyphilis, however, showed cerebral blood flow and cerebral metabolic rate of oxygen values which were abnormally low in the afebrile state but which increased on the average by 30% and 24% respectively during fever. Although cerebral blood flow remained unchanged in asymptomatic neurosyphilis, dilatation of cerebral vessels must have occurred, since cerebral blood flow remained unchanged despite significant decreases in blood pressure. Furthermore, in the group with general paresis, cerebral blood flow increased despite the decrease in blood pressure, which can only be attributed to cerebral vasodilatation.

In the present experiments, cerebral venous outflow remained essentially unchanged until a temperature of 39.0-39.4° C. was reached; then it increased steadily and significantly. Undoubtedly the increase in cerebral venous outflow was partly due to the rise of blood pressure. The progressive decrease in cerebral vascular resistance, however, indicated that the rise of blood pressure was not the major factor, but that considerable cerebral vasodilation occurred during induced fever, probably related in part to increased carbon dioxide production during fever, as evidenced by the increase in expired carbon dioxide levels.

Cerebral metabolic rate for oxygen increased significantly at 40-42° C. The increase was larger if values in the steady state were low, since values at 40.0-42.0° C. became uniform. The average increase in cerebral oxygen metabolism was 35% and correlated well with the average increased cerebral blood flow of 30-50%.

If the temperature was increased beyond 42° C., cerebral venous outflow and cerebral oxygen metabolism decreased rapidly and the electroencephalogram deteriorated. Under the conditions of these experiments the

critical body temperature for maintenance of cerebral circulation and function appeared to be around 42° C. (107.6° F.).

When hyperthermia (around 41° C. rectally) was maintained for 60-80 minutes, both cerebral blood flow and cerebral oxygen metabolism tended to decrease with progressive deterioration of the electroencephalogram. These results are in good agreement with *in-vitro* studies of the oxygen metabolism of the rat brain by Looney and Borkovic and by Himwich et al.,⁶ which also showed that both the level and the duration of hyperthermia were important in determining its effects on cerebral metabolism.

The results reported here are consonant with the conclusion that hyperthermia increases cerebral metabolism and blood flow between 39° C. and 41° C. Above this temperature cerebral metabolism and blood flow are reduced, presumably due to cerebral enzymatic damage.

Summary

1. Hyperthermia was induced by a heating-pad in immobilized, regionally anesthetized, artificially ventilated rhesus monkeys.
2. Cerebral blood flow remained un-

changed until rectal temperatures of 39.0-39.4° C. were reached. After this, cerebral blood flow increased steadily until a maximal increase of 30-50% was obtained at 41.5-41.9° C.

3. Cerebral oxygen consumption increased significantly during hyperthermia, the average increase in cerebral oxygen metabolism at 40-42° C. being 35% of the steady state.

4. Although the increase in cerebral blood flow and cerebral oxygen metabolism was significant, they appear to be relatively less than the large increases found in other organs and tissues.

5. Above 42° C. cerebral venous outflow and cerebral oxygen metabolism suddenly decreased and the EEG deteriorated progressively.

6. If body temperature was maintained at moderate levels of hyperthermia (ca. 41° C.), cerebral venous outflow and cerebral metabolic rate for oxygen progressively decreased and the EEG became progressively abnormal despite maintenance of constant temperature.

It's the Law

A SUMMARY OF EXISTING LEGISLATION IN REGARD TO THERAPEUTIC ABORTION IN THE UNITED STATES.

PREPARED FOR THE MINNESOTA OBSTETRICAL AND GYNECOLOGICAL SOCIETY MEMBERS, ROCHESTER, MINNESOTA, APRIL 23, 1966.

A therapeutic abortion is an abortion performed out of necessity. All of the states have criminal statutes dealing out severe penalties for criminal abortion, but, with one or two exceptions, each state has recognized necessity as justification.¹

The majority of the states, 41 to be exact, agree that an abortion is allowable if it is performed "to save the life of the mother." Twenty-five of these states flatly exempt from criminal liability the situation where an abortion is necessary to save the mother's life.²

Nine states: Connecticut, MINNESOTA, Missouri, New York, South Carolina, Virginia, Washington, West Virginia and Nevada carry their statutes a step further and exempt abortions necessary to "save the life of the mother or her child."³

Eight states: Florida, Georgia, Kansas, Mississippi, Wisconsin, Nebraska, New Hampshire and Ohio neglect to mention the child, yet are liberal enough to negate any notion of criminal liability per se.⁴

Two states stand out among the rest for their lack of exception. Louisiana flatly recites a statute making all abortions criminal. The Louisiana Medical Practice Act does, however, set forth the grounds upon which a doctor's license may be revoked, and this includes "any abortion unless it is done for the relief of a woman whose life appears in peril after due consultation with another physician." This does not express authorization but it does suppose that this reasoning could be construed as permissive.^{5,6}

Pennsylvania is the other state notable for its conservative stand. This state does, however, qualify the crime of abortion with the word "unlawful," thereby impliedly recognizing the possibility of a lawful abortion.⁷ There have been no Pennsylvania cases which have defined this term in relation to the statute.

Seven jurisdictions: Alabama, Colorado, District of Columbia, Maryland, Massachusetts, New Jersey and New Mexico,⁸ and also the Model Penal Code of the American Law Institute either definitely or apparently take the liberal viewpoint that necessity grave enough to warrant therapeutic abortion lies in the danger to the HEALTH of the mother.

Specifically, the jurisdictions state:

Alabama: . . . "unless the same is necessary to preserve her life and health and done for that purpose. . . ."

Colorado: . . . "unless it is done to save the life of the woman or to prevent serious and permanent bodily injury to her."

District of Columbia: . . . "unless the same was done as necessary for the preservation of the mother's life or health."

Maryland: . . . "providing that no other method will secure the safety of the mother."

Massachusetts: . . . "unlawfully." The Court held that "if a physician in good faith believes the abortion to be necessary to prevent serious impairment of a patient's mental or physical health, the abortion is considered justified."

New Jersey: . . . "without lawful justification." The Court held that the statute was designed" . . . not only for the protection of the unborn child, but to protect the life and health of the mother as well."

New Mexico: . . . "an abortion may be lawfully permitted to preserve the life of the woman or to prevent serious and permanent bodily injury."

State of Minnesota Statute:⁹

Every person, who with intent thereby to produce the miscarriage of a woman, unless the same is necessary to preserve her life, or that of the child with which she is pregnant, shall (1) prescribe, supply, or administer to any woman, whether pregnant or not, or advise or cause her to take, any medicine, drug, or substance; or (2) use, or cause to be used, any instrument or other means, shall be guilty of abortion and punished by imprisonment in the state prison for not more than four years or in a county jail for not more than one year.

Whoever shall manufacture, give, or sell an instrument, drug or medicine, or any other substance, with intent that the same may be unlawfully used in producing the miscarriage of a woman, shall be guilty of a felony.

A pregnant woman who takes any medicine, drug, or substance, or uses or submits to the use of any instrument or other means with intent thereby to produce her own miscarriage, unless the same is necessary to preserve her life, or that of the child whereof she is pregnant, shall be punished by imprisonment in the state prison for not less than one year nor more than four years.

Recommended or Proposed Minnesota Criminal Code 1963:*

A therapeutic abortion is justified (a) if performed by a licensed physician, (b) if performed in a licensed hospital and (c) any of the following conditions exist: (1) rape, (2) necessary to save the life of the mother or avoid grave impairment of the physical and mental condition of the mother or to prevent birth of a child with grave physical or mental defects and (d) if approved by two other physicians.

Recommendation of the American Law Institute in its Model Penal Code of 1959:

"A licensed physician is justified in terminating a pregnancy if (a) he believes that there is substantial risk that continuance of the pregnancy would gravely impair the physical or mental health of the mother or that the child would be born with a grave physical or mental defect, or the pregnancy resulted from rape . . . or from incest and (b) two physicians, one of whom may be the person performing the abortion, have certified in writing their belief in the justifying circumstances, and have filed such certificates prior to the abortion in the licensed hospital where it was to be performed or in such other place as may be designated by law."

In 1953, a judge in Oregon declared "that the interpretation by physicians of what is good for a woman's health takes precedence over any restrictions that are imposed by criminal law."¹⁰

There has never been a single case reported of a conviction of a physician for the performance of an abortion if the abortion was done in a licensed hospital.^{11,12,13}

In no state is potential deformity of the fetus an acceptable excuse for abortion.^{1,12}

*The above proposal was defeated in Committee and did not reach the Legislature for a vote.

PRESIDENT'S LETTER

President's Letter Continued from Page 9

we are really trying to make this a very worthwhile postgraduate meeting for each of you, regardless of your specialty. The entire program attempts to cut across as many fields as possible.

There will be no banquet on Monday this year. Rather than plan anything else, we thought that you might like to have a free evening for a change, to get together with old friends, have a whing-ding, or both!!!

In view of the current battle now being

waged in the California courts by the physicians of that state, who believe their abortion laws to be antiquated, I should be remiss if I did not call to your attention numerous viewpoints on that subject expressed in this issue of your journal.

C. G. Sheppard, M.D.
President
Minnesota State Medical Association

Legislation Voted Upon by Minnesota Obstetrical-Gynecological Society*

State of Minnesota Statute

Every person, who with intent thereby to produce the miscarriage of a woman, unless the same is necessary to preserve her life, or that of the child with which she is pregnant, shall (1) prescribe, supply, or administer to any woman, whether pregnant or not, or advise or cause her to take, any medicine, drug, or substance; or (2) use, or cause to be used, any instrument or other means, shall be guilty of abortion and punished by imprisonment in the state prison for not more than four years or in a county jail for not more than one year.

Whoever shall manufacture, give, or sell an instrument, drug or medicine, or any other substance, with intent that the same may be unlawfully used in producing the miscarriage of a woman, shall be guilty of a felony.

A pregnant woman who takes any medicine, drug, or substance, or uses or submits to the use of any instrument or other means with intent thereby to produce her own miscarriage, unless the same is necessary to preserve her life, or that of the child whereof she is pregnant, shall be punished by imprisonment in the state prison for not less than one year nor more than four years.

Recommendation of the American Law Institute in its Model Penal Code of 1959:

"A licensed physician is justified in terminating a pregnancy if (a) he believes that there is substantial risk that continuance of the pregnancy would gravely impair the physical or mental health of the mother or that the child would be born with a grave physical or mental defect, or the pregnancy resulted from rape . . . or from incest and (b) two physicians, one of whom may be the person performing the abortion, have certified in writing their belief in the justifying circumstances, and have filed such certificates prior to the abortion in the licensed hospital where it was to be performed or in such other place as may be designated by law."

Psychiatric Indications for Abortion*

Pro

ABORTION IS one of the most emotionally charged subjects upon which I have ever had to write.

We can say that there are very few indications for abortion; we can say there are no indications for abortion. To turn our back on the problems by pronouncing that there shall be no abortions, that there are little or no medical indications for abortion, is, to me, an absurdity of astounding proportions. And yet, for the most part, our laws and a considerable number of our professionals seem to insist that this be the case. Such insistence is the denial of certain natural laws, a denial of certain inalienable truths, and such denial does not behoove the man of science. The voice of the people may well resolve the problem, and those of us who get mired in the arguments may well awaken to find the matter resolved by others, much to our consternation and perhaps relief.

An understandable but deplorable dilemma in this whole situation is the stand we medical men take; all too rarely do we ask others outside the profession to help us. The dilemma is seen in the position we take when we ask: 1. What are the psychiatric indications for an abortion? 2. What are the medical indications for an abortion? 3. Can you prove that an abortion will

save this mother's life? 4. Can you prove that an abortion will not damage the health of the mother, i.e., lead to depression, sterility, or frigidity?

What I am trying to get at is that our framework for making decisions appears to be too narrow. This narrow framework is what has made us decide at certain times that all schizophrenic women should be aborted or sterilized. It is easy to find schizophrenic symptomatology, but I don't know if any studies indicate that even a majority of the schizophrenic women make bad mothers or reject their infants.

A very deplorable thing adding to the polarization of opinions into sharply defined pros and cons is the secretive nature under which our evaluations, our operations and our conferences have to take place. In doing so, we would appear to be involving ourselves in both a social and psychological injustice.

Statistics of various sorts have found, over the past 80 years, that one condition after another has been at the head of the list as an indication for abortion. Claims have been made that medical reasons have been used to justify abortions when socio-economic pressures were the real reason. I believe this is true.

If medicine has been used to justify the many abortions motivated mainly by socio-economic pressures, then Dr. Joseph Ryan**

REGIONAL WEATHER FORECAST

Severe Snow Storms, Strong Winds and Bitter Cold Followed by Cough, Stuffed and Runny Noses and Aches and Pains.

Tussagesic breaks up coughs, quickly clears stuffed and runny noses and relieves aches and pains. Provide coverage of the tough cold for up to 24 hours with just a single timed-release tablet dosed morning, midafternoon and at bedtime.

each

Tussagesic[®]

timed-release tablet contains:

Triaminic [®]	50 mg.
(phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. **Side effects:** Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. **Precautions:** The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

DORSEY LABORATORIES • a division of The Wander Company • LINCOLN, NEBRASKA

does not understand the motivating significance of socioeconomic pressures. He would appear to be responding to a type of moralistic pressure, which in decades gone by led to the legislation of prohibition of intoxicating beverages. I do not consider prohibition a justifiable legislation.

I hear the argument that until the lawmakers change the laws we should not break the existing ones. I would support legal changes, but what changes should be made? If causes for the inevitable abortion are mainly socioeconomic, should the doctors be the only people to make the decisions about individual cases? Should the doctors be involved at all in making decisions, since they would be doing many of the abortions? Should we not legislate a hospital abortion board composed of a doctor, a social worker, and a lawyer knowledgeable in the subject, including specific philosophy pertaining to the indications. This would seem to be far superior to a secretive two-doctor panel. It would have the advantage of consistency, collection of statistics and follow-up studies on a mass scale. After all, does not good legislation mediate liberty, justice, and equality?

Leaving out eugenic reasons for abortions

I believe that the psychiatric indications for abortion are:

1. Severe chronic illness, in any diagnostic category, in which there is usually no reason to expect emotional profit for the mother-child unit.

2. Pregnancy occurring in a never married professional woman above 35 years of age when the woman is clearly unable to deal with this aspect of life, i.e., marriage and child rearing and the shame of being pregnant.

3. Pregnancy occurring as the result of rape or incest, or severe mental illness or mental retardation where the woman cannot be expected to be held responsible for conception, or in the case of incest where the process becomes fixed if not interrupted and the child is stigmatized beyond repair.

4. Recognizing that we cannot separate clearly socioeconomic pressures from psychiatric disturbances, I would include abortion for the woman who has had "too many children," and wishes to do something about it. Here sterilization is also to be considered.

I am not advocating compulsory or forced abortion. It should be an enlightened voluntary matter.

Richard R. Teeter, M.D.
St. Paul, Minnesota

Psychiatric Indications for Therapeutic Abortion*

Con

SINCE WORLD WAR II psychiatrists have oversold themselves. Because of this, many people feel that their skills should be used to solve social, economic, and political problems, and that they should have the right to interpret laws as they see fit. Thus, some psychiatrists have concluded that they can decide who should have a therapeutic abortion, regardless of the law. Bolter¹ abhors this conclusion and states directly and clearly, "Psychiatrists have no more right to break the law than anyone else in our society."

If a decision is made, not on emotions, but

on the basis of medical knowledge only, and within the law, then there are no psychiatric indications for therapeutic abortion.^{2,3} More appropriately, the function of a psychiatrist in this field should be to determine if a patient can tolerate, from the psychiatric point of view, an abortion which is indicated for other than psychiatric reasons, since termination of pregnancy is not without psychiatric risk. Sim³ states, "Abortion, even if therapeutic, may in itself produce a psychosis." Noyes and Kolb⁴ say, "As high as one fifth of the women allowed therapeutic abortions later expressed regret for accepting the procedure."

*Part of the Symposium on Therapeutic Abortion read at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, April 23, 1966.

LABSTIX

new from Ames 5 basic uro-analytical facts in 30 seconds

Labstix®

BRAND REAGENT STRIPS

...broadest urine screening possible from a single reagent strip

Urine test results with LABSTIX Reagent Strips can represent significant guides to differential diagnosis or therapy in many conditions. An unexpected "positive" may enable you to detect hidden pathology — long before more recognizable symptoms become evident. Negative results, which permit you to rule out abnormalities in a broad clinical range, can serve as baseline values for reference in future examinations. The 5 colorimetric test areas encompassed on LABSTIX Reagent Strips are:

pH — values are read numerically in the essential range of pH 5 to pH 9.

Protein — results are read either in the "plus" system or in mg. % in amounts approximating "trace," 30, 100, 300, and over 1000 mg. %.

Glucose — provides a "Yes-or-No" answer for urine "sugar spill."

Ketones — detects ketone bodies in urine — both acetoacetic acid and acetone. Reacts with as little as 5 to 10 mg. % of acetoacetic acid.

Occult Blood — specific test for intact red cells, hemoglobin or myoglobin. Results are read as negative, small, moderate or large amounts.

Now a Clear Reagent Strip of Firm Construction

...facilitates handling during testing procedure. Excellent color contrast made possible by the clear plastic strip, together with the clearly defined color charts provided, permits precise, reproducible colorimetric readings in all 5 test areas. A more definitive interpretation of uro-analytical facts is made possible.

Available: LABSTIX Reagent Strips, bottles of 100 (color charts are supplied with each bottle).

Ames Company, Inc., Elkhart, Indiana

AMES

In the State of Minnesota the only reason for performing a therapeutic abortion is to preserve the life of the mother or the child. Thus, the principal criteria for psychiatric consideration for termination would be the likelihood of suicide. Interestingly, since the institution of the Maternity Mortality Study in Minnesota there have been only 14 suicides in approximately 1.5 million births.⁵ Statistically this is less than would be expected from any 1.5 million subjects. In a New York City Study⁶ it was observed that proportionally fewer pregnant women commit suicide than those who are not pregnant.

In a British study³ of 1963, which investigated a seven-year period in the City of Birmingham, not one pregnant woman committed suicide. In a California study⁷ of three counties (San Mateo, Santa Clara, and San Francisco) of ten million people in 1961, 1962, and 1963, three instances of suicide by pregnant women were found. This figure was compared with the statistically predicted figure for women of child-bearing age in the three counties. The "actuarial" expectancy of suicide was determined to be 17.6 for the group involved. The explanation of why so few pregnant women commit suicide may be due simply to the fact that pregnant women — including unmarried ones — get considerable more attention from society when pregnant than when not. Studying the case histories of the suicides in the Minnesota study, it is clear in retrospect that the 14 suicides probably could have been prevented if adequate psychiatric care had been obtained and utilized. The most tenable psychiatric diagnoses in these 14 cases are either psychotic depressions or schizo-affective types of schizophrenia, for which there are fairly adequate treatment modalities.

Even though the law in Minnesota now states that the only indication for therapeutic abortion is to preserve the life of the mother or child, consideration should be given to the effect of pregnancy on the future health of the mother, which some authorities wish amended to the law. Noyes and Kolb⁴ state, "Experience does not show that pregnancy and birth of the child in-

fluence adversely the course of schizophrenia, manic-depressive illness, or the majority of the psychoneuroses." Zillboorg⁹ says, "Pregnancies that are marked by psychological tensions, severe moods, and anxieties are not really abnormal pregnancies, and common sense to the contrary, the so-called psychologically uneventful, serene, and sunny pregnancies are apt to be harbingers of severe and even malignant post-partum reactions. This does not mean that all psychologically uneventful pregnancies are forerunners of post-partum psychoses, but they frequently may be — whereas the so-called psychologically stormy pregnancies seldom are such forerunners." He concludes therefore that on purely clinical grounds it is impossible to predict who might and who might not develop a post-partum psychosis. In practice the typical woman who develops such a psychosis is not one who wanted an abortion, but is rather an obsessive, compulsive patient: for example, a married woman with a strong moral code who had a planned pregnancy and who is considered to be a good mother by her peers.

In relation to what occurs post partum, consideration must be given to what happens if a therapeutic abortion is done for psychiatric indications. In a 1965 Swedish study⁹ of 57 cases of abortion (legal, illegal, spontaneous) Jansson reports that psychiatric difficulties were much higher after legal abortions than after illegal and spontaneous abortions. In this study, as in other studies, it appears that those who supposedly need the abortion most for psychiatric reasons develop the most psychiatric complications after the abortion. It could therefore be deduced that those patients who can tolerate a therapeutic abortion do not need it in the first place. In Lindberg's study¹⁰ of 304 patients whose request for therapeutic abortion had been refused, not one committed suicide, although 62 indicated they would if their request was refused. In a series reported by Dr. Hooks¹¹ of Sweden, who investigated 249 cases who were refused legal abortion, there also was not a single suicide, even though seven women

Mike expects a penicillin injection. He's about to be pleasantly surprised.

His physician is going to prescribe an oral penicillin —PEN•VEE® K (potassium phenoxymethyl penicillin). It's usually so rapidly and completely absorbed that therapeutic serum levels are produced in 15 to 30 minutes. Higher serum levels generally last longer than with oral penicillin G.

Indications: Infections due to pathogens susceptible to oral penicillin G. Prophylaxis of rheumatic fever in patients with previous history of the disease.

Precautions: Skin rash, symptoms resembling those of serum sickness, or other manifestations of penicillin-allergy may occur. Measures for treating anaphylaxis should be readily available: epinephrine, oxygen and pressor drugs for relief of immediate allergic reactions; anti-

histamines and corticosteroids for delayed effects. Penicillin may delay or prevent the appearance of primary syphilitic lesions. Patients with gonorrhea who are suspected of concurrent syphilitic infections should be tested serologically for at least 3 months. Where lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. As with other antibiotics overgrowth of nonsusceptible organisms may occur; if so, discontinue and take appropriate measures. Treat β -hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent development of rheumatic fever or glomerulonephritis.

Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity

Composition: Tablets—125 mg. (200,000 units) and 250 mg., (400,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

Wyeth Laboratories Philadelphia, Pa.

ORAL **PEN•VEE® K**
(potassium phenoxymethyl penicillin)

in the series had previously made attempts unassociated with pregnancy. He judged that two thirds of the 213 women who bore the children had become well adjusted.

In summary, there are no psychiatric indications for therapeutic abortion because

1. Suicide is less of a risk in pregnancy than in non-pregnant women.

2. It is impossible to predict who will develop a post-partum psychosis.

3. Adequate treatment methods are available to handle psychiatric difficulties occurring during pregnancy.

4. Therapeutic abortion has its own psychiatric morbidity.

Irving C. Bernstein, M.D.
Minneapolis, Minnesota

Why Therapeutic Abortion?

DURING THE PAST few decades the medical profession as well as the general public have liberalized their attitudes towards sterilization and the use of contraceptive devices. World-wide attitudes aided by scientific developments have yielded to the pressures of population, economics, and sophistication so that many members of religious groups and sects formerly opposed to these ideas are beginning to accept the new and more reliable forms of contraception. The same pressures are now being brought to bear on our abortion laws. This is not only a medical problem, but a moral issue that eventually will be decided by the populace, led and guided by our religious leaders, doctors, social workers, lawyers and perhaps (overlooked before) mothers.

Since physicians will be the instruments through which the law will act, it is of utmost importance that physicians as a group, obstetricians in particular, play a vital role in determining these inevitable changes. A great deal of credit should be bestowed on the Minnesota Obstetrical and Gynecological Society and particularly essayists in the Minnesota Medicine for their timely and careful study of this problem. They have at-

tempted to rise above the emotional levels involved and to present facts as each individual sees them.

There remain three reasons why a pregnant woman will present herself to a physician for therapeutic abortion: (1) To terminate or avoid harmful effect of gestation and parturition on maternal health, (2) To prevent birth of an unwanted child, (3) To prevent birth of a damaged infant.

Evidence presented in these papers would indicate that widely quoted figures of death due to septic abortion and suicides caused by an unwanted pregnancy have been exaggerated, also that there are few medical conditions that would result in death because of the pregnancy. In spite of this over 60% of the Minnesota Obstetrical-Gynecological Society members and the Minnesota Psychiatric Society members who answered the questionnaire on indications for therapeutic abortion would recommend changes in the Minnesota Statutes as they now read, so that they would include other than maternal life as an indication for therapeutic abortion. Apparently these physicians do not

agree with the psychiatrist who believes categorically that there are no psychiatric indications for therapeutic abortion.

Surely the goal of medicine is more than to preserve life. It must be to preserve the life of a person with as little physical and emotional pain as possible. It is no longer possible to separate the psyche from the soma, so one must treat the person as an entity including both of these component factors.

This is a moral, as well as a medical problem. The law, as it now stands, permits an abortion if the life of the mother is in jeopardy. This is perhaps consistent with the quotation from Albert Schweitzer, who states, "Man comes again and again in the position of being able to save or preserve one's own life or life in general at the cost of other life." Everyday instruments of local and federal government make decisions justifying the killing of rioters and other violators of the law to protect the public. It is interesting that in October of this year the Lutheran hierarchy sanctioned the war in Viet Nam where there are as many civilians killed each day as there are military personnel. At the same time the Lutheran hierarchy have sanctioned therapeutic abortion for reasons other than maternal life. In medicine we frequently make decisions involving early termination of pregnancy in various stages of gestation in order to give life to the offspring, sometimes at the cost of maternal life and longevity. Likewise, we make decisions as to whether to enlist palliative measures to make life more tolerable while it lasts. It appears that a consideration of the mother's health, as well as her life as an indication for therapeutic abortion, is an extension of the same philosophy.

The other aspect of this moral problem is that there are many nations in Europe and Asia who do not look at abortion as the taking of a life, for instance, such ethical nations as Japan and Sweden. This history of our own Christian church would indicate that the idea that life begins before fetal activity is relatively a modern one. Saint Thomas Aquinas in the 13th century held that the soul was directly cre-

ated by God and was infused in the embryo, not at the point of conception, but when the embryo was sufficiently formed to receive it. This allowed the medieval church to forbid abortion only after quickening. Pope Gregory V in 1591 designated quickening to occur after 116 days. It is interesting to note that Islam considers life to begin at 180 days of gestation. The exact time life begins, then becomes a matter of definition and not of what is absolutely right or wrong. No one can demand from those who disagree with these indications for therapeutic abortion that they perform an abortion; one could only consent to do an abortion when the criteria to do so would satisfy one's own medical and moral judgment. Conversely, does one have the right to prohibit other ethical people from performing this act, if they consider the act moral and medically indicated and the action is approved legally?

Our present restrictive laws are making hypocrites of physicians who are performing an occasional therapeutic abortion for rape, incest, or pregnancy in children, or for mothers of an unborn child who is likely to be deformed. There are millions of abortions done illegally each year, mostly in married women, that jeopardize the health and life of the mothers. These conditions favor the wealthy who can afford the abortion fees or who can travel to a distant country to have a therapeutic abortion performed in a reputable hospital. It is granted that the law will be difficult to set up in a manner to prevent irresponsibility, but already our sterilization regulations have a pattern similar to that proposed in the penal code of 1954 for abortion.

The need for therapeutic abortions can be greatly reduced by recommending sterilization more frequently when indicated, and by disseminating contraceptive information throughout the world and the United States, making it more available for the needy and indigent people in particular.

Liberalization of our therapeutic abortion laws is inevitable. It is important that physicians have a strong voice in these changes,

Thiazide and Aldosteronism

INTERESTING DEVELOPMENTS abound in the field of hypertension. One of the most intriguing is the suggestion by Conn¹ that a sizeable number (1/5th) of patients with unsolved hypertension may have primary aldosteronism (from adrenal cortical tumor). This he deduces from the fact that about 20% of hypertensives have shown a marked reduction of plasma renin,² as in primary aldosteronism.

Hawley and Tobian³ report the interesting observation that administration of thiazide

diuretics to a human with hypertension and an adrenal cortical adenoma precipitated the symptoms of hyperaldosteronism by a severe reduction of plasma potassium, which produced muscular weakness so severe that the patient could not stand up.

All of this suggests that we should not blithely attribute a severe hypokalemia following thiazides solely to the drug, but should alertly look through the pharmacologic veil for an adrenal cortical adenoma.

Rolf Andreassen, M.D.

Long-Term Anticoagulant Therapy of Myocardial Infarction

ANTICOAGULATION in acute myocardial infarction has become standard therapy for the hospitalized patient. Only when there exists some contraindication are anticoagulants usually withheld. After leaving the hospital, patients in this area within reach of a medical laboratory are usually continued on long-term oral anticoagulants. However, the value of this long-term therapy is doubtful.

Marple and Wright's study¹ of 800 patients, a controlled series, concerns the first six weeks after myocardial infarction. Their significant findings in favor of anticoagulation cover this early period only and cannot be extrapolated. Bjerkelund's controlled long-term study² shows significant differences in recurrence and in mortality in favor of the dicumarol-treated group only during the first year. Bearman et al.³ show no more favorable mortality in anticoagulated patients after leaving the hospital. The mean death rate after three months for the bal-

ance of a year was 0.03 per cent per day in treated and control groups.

Prolonged anticoagulation bears a load of iatrogenic difficulties. In this journal recently Reece⁴ discussed eight serious bleeding complications of anticoagulant therapy that occurred in one hospital in a period of 18 months.

Askey⁵ mentions cerebral hemorrhage as the most serious of these complications, occurring chiefly in hypertensives; more frequent but less serious were gastrointestinal hemorrhages. Hemorrhagic complications occur within the so-called therapeutic range of increased prothrombin time. There is always a question whether the prolonged prothrombin time is the major factor in a hemorrhagic complication. Often, as in hemorrhages of the gastrointestinal system, an ulcer is demonstrated. The role of the anticoagulant cannot be discounted even though such an

Continued

"All Otolaryngologists are Alike"

Just look at them and you can see how much they have in common. Besides, they all go through pretty much the same training, and pass the same kinds of tests, and measure up to the same sort of standards. Therefore, all otolaryngologists are alike. Right?

Wrong! But that's no more preposterous than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more exacting. In fact, there are at least nine *specific differences* involving moisture content, purity, potency and speed of tablet disintegration,

which make the manufacture of Bayer® Aspirin so different.

These Bayer standards result in significant product benefits, including gentleness to the stomach and product stability, that enable Bayer Aspirin tablets to stay strong and gentle until they are taken.

So next time you hear someone say that *all* aspirin tablets are alike, you can say, with confidence, that "it just isn't so."

You might also say that all otolaryngologists aren't alike, either.

obvious hemorrhagic source as a peptic ulceration is found. The physician must also accept some responsibility for hemorrhage associated with over-dosage of anticoagulants whether so prescribed or taken in error.

Seaman et al.,⁶ of the University of Oregon, at the American Heart Association meeting October 1966 in New York reported negative results in a ten-year controlled study of the value of oral anticoagulants in long-term post-myocardial infarction therapy. Their study included 255 patients divided into three nearly equal groups: Group A, anticoagulated; Group B, placebo-treated; and Group C, not treated. There was no significant difference in recurrence of infarcts or in death rates among the three groups.

Long-term anticoagulant therapy after myocardial infarction has shown how eagerly these patients accept the regular and frequent visits to their physician. Not the least of the value of such close follow-up is in the field of psychiatry and psychotherapy. The

patient, host to a potentially lethal disease, has overcome it and is doing all he can to prevent its recurrence. It is suggested that physicians consider maintaining the value of the frequent follow-up visits without resorting to the blood-letting ceremony of the prothrombin determination and the exhibition of popular but unproved and possibly dangerous medication.

Currently in many medical centers throughout the United States a large group of post-myocardial infarction cases is being cooperatively studied. In this area this study is under way in Rochester at the Mayo Clinic; at Mount Sinai Hospital, Minneapolis; and at the Marshfield Clinic in Wisconsin. Only patients not currently anticoagulated will be included in this investigation. If long-term anticoagulation therapy is of doubtful value in myocardial infarction, cessation of such therapy within or without such a study is reasonable.

Unwanted Pregnancies

IN HANDLING unwanted pregnancies, obstacles and complexities soon become apparent which when given contemplative consideration can lead to the conclusion that the problem permits of no single easy solution. The obstetric practitioner discovers early that attitudes toward pregnancy generally may be vagarious and not infrequently in some individuals capricious. An unwanted pregnancy at eight to ten weeks, may at sixteen or twenty weeks become a desirable and an anticipatory one. Variables of this nature are inherent to many normal pregnancies, and would have a greater relevance if, as has been implied, abortion laws should be revised to permit women to be aborted legally at their request.

Dr. Decker* presents a list of the illnesses most commonly complicated by pregnancy and clearly demonstrates that with continuing medical progress the indications for therapeutic abortion will become increasingly narrowed. These and other diseases less commonly complicated by pregnancy involve little if any legal entanglement when the operation is to be performed. Likewise, ethical standards are not violated, and except for certain religious beliefs no moral transgressions are committed.

Therapeutic abortion per se in Minnesota is not hampered by legalities. Within the generality of the law a physician is free to exercise his judgment. Hospitals likewise enjoy this freedom, but for the protection of themselves and their staff members vari-

BLUE SHIELD
OF MINNESOTA

ous hospitals have established consultative procedures peculiar to therapeutic abortion. Granted that the statute pertaining to abortion could be revised, we doubt that accredited hospitals would change their regulations concerning the procedure. Certain proprietary hospitals might welcome the change, but we are not plagued with such institutions in Minnesota.

When pregnancy is unwanted for social, economic, or whatever reasons other than medical indications, however, the law becomes restrictive. Dr. Lyon* apparently advocates a release from the restrictions and implies that any physician should be free to perform an abortion at any time, for any reason, and designate it therapeutic. He has utilized certain statistics to support his thesis, the accuracy of which we question. For instance the statement "the fact that 20% of all pregnancies are illegally aborted" is in serious error. Although 20% of all pregnancies do terminate in abortion, most of them are spontaneous and may or may not require instrumentation for completion. Also "it is known that between 5,000 and 10,000 women die each year in the United States from—criminal abortions." This statement is without foundation and would be considered ridiculous by statisticians. Dr.

Barno,** working with Minnesota material, fully refutes this. The Minnesota Material Mortality Study is as comprehensive, as complete, and, through its mechanics of gathering and considering statistical material, as authentic as any that can be exhibited by a governmental unit in this country.

Unwanted pregnancy is not a modern problem. It is a predicament as old as recorded history. Nor will the probity of its handling in all cases be forthcoming soon.

English and American jurisprudence has its origin in a consensus of moral precepts which have evolved through Judeo-Christian philosophy. No law will satisfy all nor will the abrogation of a law resolve all problems. Dr. Decker aptly states that "only when we as individuals are sure of real benefit to the pregnant woman can we bring ourselves to interrupt the pregnancy." Our present law—poorly worded as some hold it to be—has served well for the majority of physicians in their obligation to themselves and to their patients. Legalizing criminality in pregnancy would no more solve the problem of unwanted pregnancy than the legalization of trespass and certain misdemeanors would resolve burglary.

You May Be Right

In the October issue of MINNESOTA MEDICINE appears an editorial by Frederic C. McDuffie, M.D.,* of Rochester, Minnesota, relating to anti-nuclear antibiotic in various diseases. He states that the results of a study by Gokcen, Peterson and Ehrnst are in serious question because they used rheumatic fever patients from several hospitals who were diagnosed by a larger number of physicians. It might be well for Dr. McDuffie to descend from the ivory tower and discover that there are physicians in Minneapolis with no connection with the great fountain heads of learning who are capable of making a diagnosis of rheumatic fever. His arrogant statement is unworthy to appear in your editorial columns.

Geo. R. Martin, M.D.
Minneapolis, Minnesota

The Editor's Soliloquy

Name-Dropping in Medical Literature

It may be commendable to cite a long list of authors in medical literature: their works, their specialties, even their biases. It may be still more praiseworthy to be able to say that one has visited their clinics and discussed with them numerous medical and surgical problems.

A short list of references in a scientific manuscript is valuable and lends dignity and authority. It serves as a take-off for an author to slip smoothly into his own monograph. It constitutes the kick-off, as it were, the toss-up, the tee-off, the first serve, the face-off, the "play ball." But when an author copies a list from another author who in turn may have copied from still another author — a progression like the little fleas ad infinitum, then the citation of copious references falls into the category of name-dropping: a common but banal practice running the gamut from the totally naive to the blatantly calculated — the latter reminiscent of the nouveau-riche female whose gown is not just a gown but a Dior and whose hat is not just a hat but a Dache.

Though name-dropping, like its counterparts of table-hopping, back-slapping, apple-polishing, *nakke fornøielse*,* or any of the other methods of currying favor, may appear to be disarming by its casualness, it is nevertheless, a subtle stratagem designed to impress the envious and gullible, to gain vicarious esteem, and to bask in reflected glory. To the discriminating, however, it is all too transparent.

Not that there is anything meretricious about excessive name-dropping, but it patently diminishes rather than enhances prestige and it definitely transgresses the bounds of good taste. Since it is punctiliously avoided by the truly cultured sophisticate, it should be likewise abnegated by the professional man.

Carl O. Rice, M.D.

Constant Linear Decrease

QUESTION: Between the ages of 20 and 80 you have referred to a constant linear decrease in the systolic wave of the ballistocardiogram, a slower rise of the carotid pulse wave, a linear rise in the time lag between the end of systole and the start of ventricular filling, and the percentage of inert pigment in myocardial fibers: these representing progressive age changes. Is it possible to defer or delay these physiologic changes by maintaining perfect health and condition throughout life?

ANSWER: There is a wide range, at ages 50 to 80, in the individual variation from the median of the age changes in the various items discussed. Some people look 10 to 20 years older at 50; some 20 to 30 years younger at 80 than the average. It is believed most of these are hereditary rather than acquired variations, and only by keeping half of identical twin pairs on differing regimens (minimal exercise, tobacco, optimal vitamin intake for one, the reverse for the other) could one establish any effect of environment on vascular aging. At the moment, the answer to the question would be: cardiac atrophy can be prevented by regular exercise; vascular aging can be hastened by chronic illness.

Benign Stricture of Common Bile Duct

QUESTION: A 50-year-old female has a benign stricture of the common bile duct following a cholecystectomy 3½ years ago. She has now developed esophageal varices. Is there a good medical regimen by which I can manage this patient or should I refer her for corrective biliary tract surgery even in the face of her portal hypertension?

ANSWER: Assuming there are no other factors to contraindicate surgery, such patients should undergo surgery aimed at correcting the stricture. The surgeon will undoubtedly elect to carry out a portacaval shunt at the same time. When corrective surgery is directed at both problems simultaneously one can expect reasonably good chances for success. Since the portal hypertension is the more immediately life-endangering problem, some surgeons would prefer to carry out the shunt procedure prior to the reconstructive biliary tract surgery.

The Viewing Box

"Bull's Eye Lesion" of the Stomach

A 62-YEAR-OLD white male was hospitalized with the complaints of shortness of breath, easy fatigability, increased weakness, weight loss, anorexia, and tarry stools.

Physical examination revealed a disoriented, emaciated man with axillary and supraclavicular lymphadenopathy, osteoarthropathy, papilledema, and multiple pigmented skin lesions on the back and buttocks. An especially large lesion on the right buttock was biopsied, and diagnosed as superficial melanoma, probably a primary lesion.

On x-ray examination of the stomach, a 5-cm. polypoid, submucosal mass was found (Figure 1 and 2), situated posteriorly, protruding into the gastric lumen, with a 3-cm. ulcer (large arrow Figure 1 and 2) at its apex. Of note was the unusually well demarcated border circumscribing the mass (small arrow Figures 1 and 2). The appearance of the entire lesion was that of a "bull's eye." The small bowel and colon were normal. A chest roentgenogram showed numerous nodules in both lungs (Figure 3).

What is your diagnosis? (See next page.)

Figure 1 (above)

Figure 2 (right top)

Figure 3 (right bottom)

DIAGNOSIS: Metastatic melanoma of the stomach and the lungs.

From 20-25% of all patients with primary malignant melanoma of the skin, mucous membranes or ocular structures exhibit gastrointestinal metastases either in vivo or at autopsy. In many cases, a gastric metastasis may first draw the clinician's attention to a long forgotten primary. These metastases are equally divided between the stomach and small bowel, the colon being virtually never involved.

Metastatic melanotic deposits to the gastrointestinal tract may present roentgenologically as multiple polypoid lesions occasionally causing intussusception, as submucosal mass lesions associated with partial or even complete bowel obstruction and peritoneal implantation or, thirdly, as gastric ulceration and perforation.

In the stomach, the secondary deposits occur in the body and fundus, the lesser curvature being seldom involved. Willis states that "gastric metastases result from hematogenous dissemination and form localized submucosal masses that grow in an exophytic* fashion to form rigid, saucer-like, polypoid-filling defects. These have a tendency for umbilicated ulceration at their tip, resulting in the central radiopaque area of the target sign when outlined with barium." The central apical ulcerations are almost exclusively seen in the gastric lesions, and seldom in the small bowel lesions, and result from the acidity and the protolytic action of the gastric contents upon the thin layer of mucosa overlying the melanotic deposit. Melanotic deposits to the stomach tend not to infiltrate laterally, accounting for the well demarcated, sharply circumscribed appearance seen on x-ray.

Willis further categorically states that "Unless a meticulous search of every part of the skin, eyes and juxta-cutaneous mucous membrane prove the absence of a possible primary growth, and inquiring elicits positive certainty that the patient has not had any skin lesion which might have been a primary source, the primary visceral origin of a melanoma can not be accepted."

The roentgenological differential diagnosis of a single polypoid gastrointestinal lesion includes spindle cell tumor, lymphoma, Hodgkin's disease, aberrant pancreas, carcinoid, eosinophilic granuloma, carcinoma, and Kaposi's sarcoma. Multiplicity of lesions is rare in any of the above, whereas it is common in melanoma. If target lesions are encountered, say in Kaposi's sarcoma or Hodgkin's disease, they are seldom as large as in melanoma. Further, melanoma is apparently the only lesion characterized by the well demarcated area of radiolucency surrounding the ulcer crater. Finally, the presence of a primary skin or ocular lesion leaves little doubt as to the correct diagnosis.

Neurological Conference

*Carpal Tunnel Syndrome**

Dr. Robert Soll**

This 53-year-old lady was referred to the University Hospitals primarily for a non-neurological problem; however, she also had an interesting neurological complaint which we will discuss today. There is another aspect to this case which we shall consider — that is, the total treatment of the patient. Therapy should not be directed solely at the patient's physical complaints, but rather it must include therapy of the patient's psychological and social needs. In this particular situation the patient finds herself in a hospital far from home. Her relatives are unable to visit her; consequently she has been extremely lonely as well as frightened in these surroundings.

History

Dr. James Zachmant†

The patient is a 53-year-old housewife who was referred to the University Hospitals February 8, 1965, with the complaint of having had several tarry stools early in January, 1965. Prior to this she had been in apparent good health. She had had no abdominal pain associated with this event. The following day her stools were normal, but on the succeeding day her stools again became black and remained so until admission to the hospital. Approximately one week prior to admission she had developed mild epigastric pain which radiated into the chest and upper arms. This pain was worse at night and had no relationship to eating. She did find that drinking milk seemed to relieve the pain; so she placed herself on a milk diet. In spite of this diet, however, her tarry stools persisted. Occasionally she had nausea and vomiting which seemed to be related to the pain. The patient's family physician performed an uppergastrointestinal series but found no evidence of any abnormality in this area. At no time did she vomit blood.

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held every Wednesday from 1:00 to 3:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward Defoe in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Held March 4, 1965.

**Department of Neurology, University of Minnesota Hospitals.

†Student Doctor, University of Minnesota Hospitals.

Continued

Another complaint that the patient had when she was seen in New Medicine Clinic was that she had had a decrease in the size of the muscle in her right thumb. She had noticed this only about a week or two prior to coming to the hospital. Recently she also had noted some numbness and tingling in her hands and lower arms on at least two occasions. About two years before this she had noted similar symptoms referable to her hands and arms, but these symptoms cleared spontaneously.

In her past medical history, she had had rather severe infections in her ears as a child. The patient's first husband died at age 50 from a heart attack and she remarried. Her present husband is 56 years old and is farming. He is having some problems with stomach ulcers.

Physical Findings

On physical examination the patient was a frail, middle-aged woman appearing somewhat younger than her stated age. Her blood pressure was 130/85 mm. Hg. and the pulse was 90/minute. She had a slight speech impediment which appeared to be due to rather prominent central incisors. Abdominal examination revealed minimal tenderness in the epigastric area and both subcostal areas. There were no enlarged abdominal masses and the stool examination was negative for occult blood. Examination of her hands revealed a rather marked atrophy of the right thenar eminence. There was a weakness of abduction of the right thumb and of opposition of the right thumb to the little finger. There was no apparent sensory deficit in the hands. The remainder of the neurological examination was normal.

The Systemic Evaluation

Medical Evaluation

Dr. Soll

Has the patient been taking any vitamin-iron preparations that might explain the presence of black stools?

Dr. Zachman: No, she has not.

Dr. Richard Magraw*

Did the abdominal pain occur at night or when she was lying down?

Dr. Zachman

It did occur at night more frequently, but she didn't think it had any relationship to lying down. She described it as a cutting pain rather than a burning pain. Also the pain did not have any relationship to exercise. She had had upper gastrointestinal x-rays and a barium enema which were normal. In addition she has been followed periodically with tests for occult blood which have been trace to 1 plus positive. Since admission she has also had a gastric analysis which was negative for free acid, but histamine provocation did induce free acid. Cholecystography revealed several stones in her gallbladder, and it was felt that this might explain some of her symptomatology.

*Director of Comprehensive Clinic, University of Minnesota Hospitals.

Dr. Soll

The cause of the melena actually has not been found. Certainly the possibility of an ulcer has not been completely eliminated, although I would agree that cholelithiasis may explain some of her symptomatology.

Neurological Evaluation

Dr. Soll

The problem of the atrophy in her right hand was worked up simultaneously along with her gastrointestinal difficulty. When we saw the patient for the first time in Neurology Clinic she had not only atrophy in her right hand but also ankle clonus. This apparent hyperactivity in the lower extremities suggested the possibility of a cervical cord lesion as a possible cause of the atrophy in her hands. In retrospect this ankle clonus may have actually been the result of anxiety and tenseness on the part of the patient. Nevertheless, one of the reasons I had recommended her admission to the hospital was to definitely determine whether a peripheral lesion or a central lesion was the cause of atrophy of the right thenar muscles. I was further faced with the problem of having to explain to her the necessity for her coming into the hospital in order to find out what was causing the trouble in her hands.

Dr. Francisco Baron*

We performed electromyographic studies on this patient and the results were compatible with a diagnosis of carpal tunnel syndrome. There was evidence of abnormalities in both the right and the left hands, but in the right hand, gross atrophy primarily of the abductor pollicis brevis was obvious.

Carpal Tunnel Syndrome

The carpal tunnel is a concavity or canal on the palmar surface of the carpal bones. It is formed by the pisiform bone and the hook of the hamate bone on the medial wall and by the tuberosity of the scaphoid and the crest of the trapezium on the lateral wall. The floor of this canal is formed by the lunate and capitate bones and is converted into a tunnel by a tough, flattened fibrous band, the transverse carpal ligament. Within this tunnel lie the flexor tendons of the fingers and thumb and the median nerve which overlies the tendons. After the median nerve passes through this tunnel, it supplies motor branches to the thenar muscles, the abductor pollicis brevis, the opponens pollicis, and the lateral head of the flexor pollicis brevis. Subsequently the nerve also supplies motor innervation to the first and second lumbricales. Lesions of the median nerve at the wrist, therefore, will affect abduction and flexion of the thumb and opposition of the thumb to the little finger. The median nerve also carries sensation from the volar surface of the thumb and most of the palm of the hand.

Initiating Factors

The carpal tunnel syndrome is not new. The condition was originally described as the "carpal tunnel syndrome" by Marie and Foix¹ in 1913.

*Medical fellow specialist, Neurology, University of Minnesota Hospitals.

Continued

In 1933 Abbott and Saunders² noted that aching and trophic changes preceded the sensory deficit. In 1947 Brain³ proposed that extension of the wrist compressed the nerve. Since many of the household tasks required extension of the wrist, he felt that this position was the likely cause of this syndrome. Many other authors have studied this problem, and the current concept is that flexion of the wrist is the principal cause of damage to the nerve. It is felt that the median nerve is subjected to compression between the flexor tendons and the transverse carpal ligament by flexing the wrist. This theory is still subject to some speculation, however, and some authors have claimed that there is a non-specific synovitis involving the synovial membrane in the carpal tunnel.

Many conditions have been related directly or indirectly to the carpal tunnel syndrome. This syndrome has been encountered most frequently in post-menopausal women; also it has been seen in myxedema, pregnancy, endocrine disturbances such as acromegaly, and amyloidosis. There is a low incidence among male manual laborers.

Clinical Observations

As far as the clinical diagnosis of this syndrome is concerned, the history will often reveal symptoms of pain, burning and tingling in the hands as some of the initial complaints. This pain will be limited to the two lateral fingers and thumb as a rule; occasionally, however, there may be radiation of pain into the upper arm and at times into the shoulder. The pain usually increases during the night and may wake the patient. Swelling and numbness of the fingers may occur and some patients note an inability to use the thumb due to weakness of the thenar muscles. They do complain of dropping articles which they are holding or of an inability to make full use of their hand. The typical patient with this syndrome is a middle-aged housewife whose dominant hand has been affected for about a year or longer. Interestingly, the carpal tunnel syndrome was initially studied as a disease confined to females. Many studies have found both sexes affected; for example, one reported by Phalen and Kendrich,⁴ 1957, cited 71 cases in which 54 cases or 76% were female and 17 or 24% were male. The age of occurrence of this syndrome is usually between 30 and 60 years. Most frequently the disease is bilateral; of the 71 cases cited above, 39 were bilateral and 32, unilateral. Of the latter 32, 23 involved the dominant hand. The differential diagnosis includes cervical osteoarthritis and herniated cervical disc, syringomyelia,* progressive muscular atrophy, trauma of the spinal cord or nerve roots, tumor or aneurysm of the cervical cord and the cervical rib syndrome.

Physical Findings

Physical findings in this condition will usually reveal atrophy in the abductor pollicis brevis; subsequently, the opponens pollicis and the flexor pollicis brevis may become involved. Sensation may be diminished over the distribution of the median nerve in the hand and fingers. In 85% of these patients percussion of the median nerve at the wrist will often elicit a sensation of tingling in the hand. This is Tinel's sign which indicates a partial lesion or early regeneration in a peripheral nerve. Experience in the interpretation of this sign is necessary because percussion of the median nerve at the wrist in a normal individual may also produce tingling

*See Test Your Word Score Page 63.

in the hand. Another special test which may be performed is the so-called "wrist flexion test." Hyperflexion of the wrist for approximately one minute will induce or accentuate numbness or paresthesias in the hand. This test may be positive in approximately 75 to 90% of the cases. X-ray examination of the wrist has been negative in approximately 95% of the cases but may be positive in those instances in which a skeletal abnormality exists as a result of a fracture of the wrist or arthritic process. Another special diagnostic procedure is the aggravation of the paresthesias in the hand by means of a blood pressure cuff applied above the level of the elbow with the pressure exceeding the systolic blood pressure. Weakness of the thumb may also be increased by this maneuver. Finally the electrodiagnosis of this condition is also being used since it has been positive in approximately 95% of cases. This is a particularly valuable procedure in the early stages of this condition at a time when surgical therapy will have the best chance of success. In mild cases numbness and atrophy are not always found; the patient may be complaining only of paresthesias. In this event a diagnosis of neuritis is often made empirically without discovering a definite cause. The conduction latency of the median nerve across the wrist may be the only objective finding.

Electromyogram Findings

The electromyogram has been employed for the past 20 to 25 years for the diagnosis of this condition, although it has been in wide use for only the last few years. We perform three tests: the conduction velocity of the median nerve across the wrist; the recording of the denervation potentials in the muscles of the thenar eminence; and finally, the conduction of sensory stimulation from the first finger to the median nerve at the wrist. Related to the motor conduction velocity, the median nerve is stimulated above the wrist and the conduction latency is recorded from two electrodes in the muscles of the thenar eminence, one in the abductor pollicis brevis and the other in the proximal phalanx of the thumb. A normal conduction delay is between 3 and 5 milliseconds. *In the presence of carpal tunnel syndrome the conduction latency exceeds 5 milliseconds.* In patients with severe atrophy of the thenar muscles, it is necessary to insert a coaxial needle electrode to record the conduction velocity; however, sometimes it is impossible to obtain a muscular response. In these patients the physical signs are far advanced and the diagnosis is not a problem; or, in unilateral cases there is often a prolonged conduction delay in the contralateral median nerve.

In the second part of the test, the electromyographic examination of the thenar muscles may be helpful in verifying denervation potentials and *reduction in number of the motor units which can be activated voluntarily.* Fibrillation potentials are not commonly seen in the carpal tunnel syndrome.

The third test that is performed in the electromyographic examination is sensory conduction. Ring-stimulating electrodes are placed around the index finger and two surface-recording electrodes are placed about the wrist. Subsequently this process is reversed and stimulation is applied above the wrist and the signal recorded from the index finger. *Patients with carpal tunnel syndrome tolerate a higher degree of stimulation than*

Continued

do normal patients. The action potential is reduced in size, and the latency which is normally between 1.5 and 3.0 milliseconds is delayed 4.0 to 5.5 milliseconds in patients with carpal tunnel syndrome.

Dr. Soll

The surgical carpal tunnel release was performed bilaterally in this patient by the orthopedic surgeons. This is usually accomplished by sectioning the transverse carpal ligament which decompresses the median nerve in the carpal tunnel. I have had made 35 mm. slides of this patient's hands which demonstrate the atrophy of the right thenar eminence as well as the site of the surgical procedure. I would like to emphasize that this particular neurological condition is one in which considerable improvement can be obtained if the diagnosis is made relatively early. On the other hand, considerable incapacitation can result, especially in those persons who depend on the use of their hands, if treatment is delayed.

Psychological Evaluation

In this patient we do have another problem aside from her physical complaints. She finds herself in a large hospital full of strange faces and quite far from home. In addition to this she may have significant problems at home which cause worry and anxiety. Her recovery may be delayed by these factors and thus prolong her total length of hospitalization. Therefore, it is the responsibility of the hospital staff to understand their patients thoroughly, so that the patients' morale as well as their physical disabilities can be improved. In this way their period of confinement may be shortened. Dr. Brantner will discuss this particular patient's psychological evaluation and tell us what significance it has in our total treatment of this patient.

Dr. John Brantner*

The patient is a very interesting person psychologically. On the Minnesota Multiphasic given by the psychometrist she appears to have a relatively mild neurotic adjustment with numerous physical complaints. She is moderately depressed, withdrawn, and introverted at the present time. I visited her myself and found her to be extremely diffident. She didn't actually refuse, but she clearly did not wish to take any of the tests; so I set them aside and started chatting with her. At the beginning I gave her one very quick intelligence test and found a mental age of 11 years. This was considerably lower than expected but there was one interesting aspect: the test consisted of 10 questions such as "give me the names of some fishes; tell me what houses are made of; give me the names of some big cities." She asked, "Do you mean any cities?" She then proceeded to answer, "New York, London, Toyko, Chicago, San Francisco and Los Angles." To name cities outside of the United States is extremely rare in mentally deficient or dull people, and this did not coincide with the other results of the tests. She is a very shy woman and expresses a great deal of self depreciation. I hope Miss Baker will give us some idea as to where this might have originated. This is the patient's first hospital experience in her 53 years. She is very frightened. After conversing with her for almost an hour I talked her into taking another fairly good quick test:

*Associate professor, Clinical Psychology, University of Minnesota Hospitals.

the Binet Vocabulary, which revealed an IQ of approximately 122. So she is an intelligent woman but one whose expression of this intelligence is marred by extreme diffidence. I went to see her again after she had had surgery. Today and yesterday she has been in considerable discomfort physically. I will continue to see her daily, at least until her family is able to be here.

Dr. Soll

There is often a great tendency for us to hasten through our examinations and treatment of patients without devoting time to their emotional needs. What you have said of this patient so far indicates that she is very much in need of reassurance and encouragement.

Social Service Evaluation

Miss Annie Laurie Baker*

This woman lives about 25 miles from where she was born in a rich farming community. In the State of Minnesota there are little pockets of foreign groups and she belongs to one of them. Her father came from the German border very near Switzerland and her mother lived in a little village near Zurich. They were married rather young and then moved to an area in Minnesota where there were a great many Swiss people. When she was a little girl she spent most of her time working outside with animals. Now she raises chickens. She noticed that she was beginning to have trouble with her hands when she was picking off the feathers. It is very important to her that she retain the use of her hands. She spent most of her young life by herself because she was the only girl with three brothers. She said that until she came to this hospital there probably had never been a day in her life that she had not been outdoors. When asked about school she stated that she was "real dumb," but she went through high school. She has been married twice but has never had any children.

She has been very worried here in the hospital. One concern is her 86-year-old mother who does all her own cooking and housework. Prior to her illness the patient visited her mother about twice a week to assist her with the housework and baking. She had asked several of her friends to look in on her mother while she was away. Also she is very concerned about having cancer. Her first husband had cancer and was treated at the Mayo Clinic. The pains in her chest and abdomen she thought were similar to his. Following his death, the patient married again. She owns the farm they live on which consists of 180 acres. They have done very well and have no big bills. During the last few years her present husband has had a nervous breakdown, which has concerned the patient as well as his family. I gathered from her remarks that they think he may be suicidal. It was difficult to learn anything more definite about his illness because the patient did not want to talk about it. Her husband also has an ulcer condition for which he is being treated. In summary, I thought she was a well integrated person although she is very depressed and has three very serious worries: she is worried about having cancer; she is worried

*Director, Social Service, University of Minnesota Hospitals.

about her husband; she is worried about her mother. For these reasons, she is very anxious to go home.

Discussion

Dr. Richard Magraw

We do a good deal of talking with students about paying attention to the whole person. Here is a good example of how easy it is for us to focus on the immediate problem that we are concerned about, thus losing sight of the fact that this "problem" is a minor incident in the patient's total life experience. For example, she has a husband at home who is suicidal. I think doctors are asking for a rather inconsequential role, if they fail to take into account the actual picture. One question I would like to ask about the neurological problem: how urgent was it to have this carpal tunnel release done? Which of the two medical problems is really of more concern, the melena or the atrophy of her hands? I would guess that probably the atrophy would not have been as pressing as the melena, but maybe I am wrong.

Dr. Soll

As things turned out, certainly the melena was the more immediate problem; however, had the patient been found to have a cervical cord lesion, very likely the neurological problem would have been the more important of the two. Nevertheless, both problems needed to be taken care of while she was here. As far as the urgency of performing a carpal tunnel release is concerned, the sooner it is done, the better.

Dr. Magraw

I would like to ask Dr. Zachman if he feels that the cause of the melena has been found or whether further diagnostic studies should be done?

Dr. Zachman

I don't see how the question of melena has been fully answered. She has had continued trace of 1+ guaiac tests throughout her hospital stay — in spite of the fact that all studies to date have been negative.

Student Doctor

A guaiac test showing a trace to 1+ is within normal limits, particularly if a patient is eating meat.

Dr. Soll

There may be many obscure causes of bleeding and resultant melena. In spite of the fact that our tests thus far have been negative I think it would be well to continue to watch for further evidence of melena; then further investigations will have to be made.

Summary

We have discussed a 53-year-old housewife who has presented an interesting complex of problems, both organic physical complaints and problems which developed due to her emotions and personality while she was in the hospital. On the one hand, she presented both a neurological problem which proved to be readily diagnosed and treated and a gastrointestinal problem which has not been as easily resolved. Although

cholelithiasis was found and could partly explain her epigastric symptomatology, it does not readily explain the presence of melena which the patient had significantly prior to her admission to the hospital. She was placed on a ulcer diet which did partially relieve her symptoms. It will be important in the future to continue to follow the patient in order to determine whether further symptomatology does occur which would require renewed testing. On the other hand, this patient also has impressed upon us the necessity for our being aware of all of her problems, both her immediate medical problems as well as her problems at home. Resolution of the latter certainly may play a significant role in the satisfactory recovery of the physical problem for which she is being treated in the hospital.

Buckle Up*

Be Alert

The responsibility for traffic safety rests squarely upon each and every driver. Most accidents are due to human, not mechanical failure.

Keep pace with the traffic. Slow driving on high-speed roads is dangerous.

Drive defensively. Watch for drivers signalling, and watch for those who don't signal.

Watch traffic around you. Be on guard for changing conditions.

Watch for traffic hazards, obstructions, breakdowns, merging traffic.

Check your speed often. You may be going faster than you think.

Reduce speed if driving conditions drop below standard.

Stay in the proper lane. Don't straddle the dividing line.

Obey posted rules and watch for route signs along the way so you will be in the proper lane to make changes without endangering traffic behind you.

At NIGHT drive at speeds that give you stopping distance within the range of your headlights.

Dim your lights when approaching cars going in either direction; this rule applies even if the highway is divided by a median strip.

*See *Minnesota Med* 49: 1761, 1966.

Medical Seminar

Trophoblastic Disease

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

THE TERM trophoblastic* disease is elusive, for its limits are poorly defined, to say nothing of its included entities. The true trophoblastic tumors — hydatidiform mole (benign mole), chorioadenoma destruens (invasive or destructive mole), and choriocarcinoma or chorioepithelioma — are described in current textbooks.

Hydatidiform Mole

The hydatidiform mole is a bizarre complication of about one of 2,000 pregnancies in the Western World and of more frequent occurrence in underdeveloped areas, specifically Formosa,^{1,2} the Philippines,^{3,4} and Mexico.⁵ In two series^{2,3} the incidence was reported to be as high as one in 82 pregnancies and one in 131 female autopsies. Although this high incidence could possibly be related to poverty and poor diet, Douglas⁶ has reported no increased incidence among the indigent population treated at Bellevue Hospital. A consistent finding has been that the mothers in the Asiatic studies are older and have more children.

Etiology

The cause of the hydatidiform mole is undetermined; the possibility of a filterable virus has been virtually eliminated.⁷ Repeated molar pregnancies occur, and Husel⁸ recently described a woman who had six consecutive molar pregnancies; he also cited another who had 18. It has been suggested that molar pregnancy is the result of re-

tention of an early abortion; however, this may be the effect rather than the cause.

Clinical Manifestations

Clinically, a molar pregnancy becomes manifest in the second trimester, most often around the eighteenth week.⁹ The patient may pass tissue, or she may present with excessive vomiting, bleeding, or toxemia, or any combination of the three. As many as 35% of patients with hydatid mole have toxemia.⁵ On examination, the uterus is usually larger than it should be considering the period of gestation and feels "tensely elastic" rather than soft.²

Diagnostic Tests

Naturally, no fetus will be detected by clinical or laboratory means, unless a twin pregnancy exists. Our British colleagues have become so astute at diagnosing the hydatidiform mole with sonar that Harper and MacVicar¹⁰ diagnosed such a twin pregnancy before the induction of labor. One or both ovaries may be enlarged, representing theca lutein or compound lutein cysts. The latter term is preferable since luteinizing granulosa cells may be part of the cyst wall.¹¹ There is some evidence that if compound lutein cysts occur after a mole is formed, there may be less of a tendency for malignant change.⁹ If a quantitative pregnancy test is done, the results will be greatly elevated. The normal limits of the test as described by Delfs¹² show that the value, which peaks at about the seventieth day, should be less than 700,000 international

*See Test Your Word Score Page 63.

Continued

units and, after the one-hundredth day, it should be within 3,000 to 30,000. In multiple gestations, the downswing will be delayed about a month. The diagnosis may be confirmed only when grape-like tissue is passed. Microscopically, there are villi with edematous and degenerated stroma but without blood vessels; the trophoblast shows varied degrees of proliferation. The microscopic picture probably is of little help in determining prognosis. Since the hydatidiform mole is avascular, only the villi adjacent to maternal circulation show cellular activity; yet these villi are the ones frequently missed on curettage.

Treatment

About 80% of molar pregnancies are uncomplicated after delivery. Usually delivery is accomplished with oxytocin stimulation, but uterine rupture has been reported.¹³ Hysterotomy is commonly used if the fundus is above the umbilicus. The use of hypertonic glucose has been reported.¹⁴ After delivery curettage should be performed; the physician must be cautious not to perforate the softened uterine wall. Perforation at such a time has been suggested as a cause of chorioadenoma destruens.^{15,16} Hysterectomy is recommended as the treatment if the patient has completed her family or is more than 40 years old; the Asiatic studies indicate that mothers who are more than 40 years old have a higher risk of developing malignancy.

Follow-up Studies

Quantitative pregnancy testing is the best method of follow-up to determine the trend of the titer of human chorionic gonadotropin. According to the observations of Brewer and associates,¹⁷ a decision probably should be made at 60 days after the mole has been evacuated, if the titer is rising or has remained constant. Naturally, dilatation and curettage should be done before this time if the patient has persistent vaginal bleeding. Uterine scrapings are often of no help; thus laparotomy or biopsy of metastatic lesions, if present, is necessary to establish a tissue diagnosis. Unfortunately in an effort to make this diagnosis, the phy-

sician may deprive the patient of future childbearing or may spread tumor cells and expose the patient to operative morbidity and possibly mortality. That sterility is not a necessary result has been shown by Wilson and associates,¹⁸ who removed isolated nodules from the uterus in selected cases. Hertz and co-workers¹⁹ and Brewer and associates,¹⁷ however, divided trophoblastic disease into nonmetastatic and metastatic and treated patients who had metastasis according to the value of the human chorionic gonadotropin titer alone. In doing so, they obviously are treating chorioadenoma destruens as though it was truly malignant.

Chorioadenoma Destruens

Perhaps a better term for this intermediate type of trophoblastic tumor would be destructive or invasive hydatidiform mole, for that is exactly what it is. When it occurs, chorioadenoma destruens always forms from a benign mole; contrariwise, about one of six benign moles becomes invasive. Microscopically, the villous architecture is retained, even in metastasis, although it may be hard to find. This is the only feature that differentiates invasive mole from choriocarcinoma, as both may cause persistent vaginal bleeding, compound lutein cysts, increased human chorionic gonadotropin titer, and metastasis. In cases of invasive mole, metastasis occurs most commonly to the uterine wall by direct extension and to the lung or vagina via the bloodstream. The prognosis is excellent, however, even in metastatic invasive mole because removal of the primary tumor cures virtually all of these patients. However, this benign metastasizing tumor may indirectly kill by hemorrhage or sepsis. One such death has been reported.²⁰ Chemotherapy will effect a cure in cases of this tumor.

Choriocarcinoma

In a discussion of choriocarcinoma, Hertz' analogy of trophoblastic disease lying on a spectrum can be considered.²¹ However, if this analogy were entirely true, invasive moles could be expected to progress to choriocarcinoma. In fact, it is the end result

of only about 3% of benign moles. About one half of the cases of choriocarcinoma result from moles, one fourth from abortions, and one fourth from normal pregnancy. Ectopic pregnancy accounts for about 2%.⁹

In undergoing this malignant change, the trophoblast loses its villi, and there is anaplastic overgrowth in varied proportions of both layers of trophoblast. There is invasion of maternal tissue, with coagulation necrosis and hemorrhage. Since this cancer is entirely dependent on free maternal blood for sustenance, the tumor nodules frequently are hemorrhagic and have necrotic centers.¹¹

Treatment

The method of treatment varies with the philosophy of diagnosis. Some physicians institute chemotherapy after histologic diagnosis, usually after hysterectomy. Others will institute treatment in cases of a persistent titer, considering the condition to be one of metastatic trophoblastic disease; they reserve surgery for unresponsive cases.

The customary chemotherapy initially includes the use of methotrexate, a "course" consisting of 25 mg. per day for five days, either orally or intramuscularly administered. Morbidity from the drug is frequent and can be monitored by means of clinical examination and the usual laboratory tests, especially leukocyte and platelet counts. The patients under treatment should be examined at least once daily for oral lesions, alopecia, reddening of old scars, or neuropathy. Death occurs infrequently and then usually only after repeated courses. That normal pregnancy is possible during the period of remission has been cited by Brewer and associates,¹⁷ McKelvey,²² and Freedman and co-workers.²³ Tumor response may be monitored each week by means of a sensitive, quantitative pregnancy test. The courses of methotrexate are repeated until toxicity is prohibitive or until the human chorionic gonadotropin titer falls to zero. When the human chorionic gonadotropin titer reaches zero, Brewer and his associates¹⁷ give two more courses to ensure remission. A promising adjuvant to metho-

trexate is actinomycin D; this drug is given intravenously at the first sign of resistance to methotrexate in a dose of 10 μ g per kg. per day for five days. Hertz and associates²⁴ reported 17 cases of methotrexate failure in which treatment with actinomycin D was used; in the 17 cases, 10 remissions were noted. Ross and colleagues²⁵ recently cited 19 patients who were resistant to methotrexate; nine of these experienced remission after use of actinomycin D. Using the drug as a primary treatment, mainly because hepatic dysfunction obviated methotrexate therapy, these authors noted remissions in three of seven patients and in eight of 14 patients in two series. Triple therapy (5 mg. of methotrexate plus 10 mg. of chlorambucil orally and 0.5 mg. of actinomycin D intravenously daily for five days) has been used in patients unresponsive to either methotrexate or actinomycin D alone.

Prognosis

Ross and associates²⁵ believe that the patient's prognosis is vastly improved if the duration of disease is less than four months and if the human chorionic gonadotropin titer is less than one million when treatment was begun.

Survival statistics are difficult to evaluate because methotrexate has been in use for only about 10 years and because investigators do not share common diagnostic criteria. For example, Ross and associates²⁵ stated that they observed remission in 76% of their cases of choriocarcinomas and in 73% of their patients with "chorioadenoma destruens and mole." Cure in the latter group is theoretically 100%. The former group probably includes cases of invasive mole. Since invasive mole occurs five times more frequently than does choriocarcinoma, the question arises concerning how many patients with truly malignant tumors are being cured. In general, about two thirds of patients with choriocarcinoma experience remission after methotrexate therapy.^{4,21,26} About 10 to 20% more respond to actinomycin D, although experience with this drug is limited.

Continued

Metastases

Pulmonary metastases in choriocarcinoma generally assume three forms.²⁷ Most frequently, discrete asymptomatic lesions are found on roentgenograms of the chest; some of these patients have painless hemoptysis. However, the roentgenogram may have a "snowstorm" appearance, which is often associated with an asymptomatic condition but an ominous prognosis. Finally, a tumor mass may embolize, with symptoms and signs typical of pulmonary embolism. The embolism may be the presenting picture, after which the malignant embolus invades. Cerebral metastasis is frequently fatal and also indicates probable resistance to chemotherapy, although there is evidence that radiation may be of benefit.²⁴

Other Trophoblastic Disease

The gestational trophoblastic tumors are only a part of the group of trophoblastic diseases and form a spectrum of disease entities. Toward the benign end is syncytial* endometritis. Although this condition probably is benign, its name indicates that it is a trophoblastic disease. Novak and Woodruff¹¹ described histologic persistence of syntrophoblast and inflammatory cells at the placental site after abortion or normal delivery. Indeed these cells may even be seen in single file between myometrial fibers, but there is no hemorrhage or necrosis. Apparently this condition must regress, for no one has described the fate of these cells.

Along the trophoblastic continuum is embolization of trophoblastic cells during a normal pregnancy. This paradox of nature was described almost 80 years ago, and the problem is yet to be solved. This potentially malignant tissue embolizes in about one half of normal pregnancies²⁸ (and probably also in aborted and molar gestations) and regresses spontaneously. If the cells retain viability and invade, they appear the same microscopically and ultrastructurally; yet the tumor is a choriocarcinoma. In any event, this process is included in trophoblastic disease because it has not been reported in 100% of maternal autopsies and

because the normal place for trophoblast is within the uterus.

In a sense, gestational choriocarcinoma does not represent the most malignant form of trophoblastic disease, since it is at least responsive to medical therapy. At the malignant end of the spectrum are testicular choriocarcinoma and teratomatous choriocarcinoma. These lesions are as aggressive as the gestational form but are refractory to any chemotherapy²⁹ and cause death virtually 100% of the time.

Current Research

There are many areas of research into the trophoblastopathies. In the field of immunology, Breyere³⁰ has devised a most provocative experiment. Groups of female mice from one inbred strain were mated with each of three different inbred male strains. Then tumor tissue from two of the male strains was transplanted into each postpartum female and into virgin females (as controls). The tumor was completely accepted (even as late as 200 days after delivery) only in those females whose mates and tumor transplant came from the same strain (Table).

TABLE
Rejection Patterns of Tumor Tissue Transplant in
Female Mice of Same Inbred Strain

Tumor Tissue From	Postpartum				Control No Mating
	Male Strain	Mated With A Strain	Mated With B Strain	Mated With C Strain	
A		Accepted	Rejected	Rejected	Rejected
B		Rejected	Accepted	Rejected	Rejected

Immunologic Tolerance

Since neoplasms can overcome small barriers to immunity, the experiment was repeated with the use of skin grafts. The results were the same, except that the skin grafts were rejected after prolonged periods of time. Three or more pregnancies provided these females with maximal immunologic tolerance; fewer pregnancies resulted in earlier rejection of the grafts. This increased tolerance may be the reason why multiparity predisposes to choriocarcinoma.

Choriocarcinoma is well known for its

*See Test Your Word Score Page 63.

occasional spontaneous regression. Also, women have been known to die from choriocarcinoma and yet have no primary tumor remaining in the uterus.¹¹ Perhaps some form of total or partial body immunity is acquired in these cases. Pierce and co-workers³¹ have shown that human choriocarcinoma from both males and females transplanted to hamsters behaves identically in growth and response to drugs. Therefore, the clinical response to methotrexate may represent the summation of the female's partial immunity to the trophoblast and the drug effects. However, trying to heighten the mother's immune response, with or without chemotherapy, has been unrewarding.^{32,33}

Patients with choriocarcinoma have increased tolerance to repeated skin grafts from their husbands. Ben-Hur and associates³⁴ have, therefore, recently suggested that, for a screening test, a woman with hydatidiform mole be given a small graft from her husband; if the graft is rejected, supposedly malignancy will not develop. Paradoxically, Mathé and co-workers³⁵ have found that patients with this increased tolerance frequently have increased antibodies against the leukocytes and platelets of their spouses. This immunologic disparity between tissue and serum is unexplained.

Consanguinity

Consanguinity has been discovered in three cases of choriocarcinoma in Beirut.³⁶ The author suggested that intermarriage is relatively common in Eastern Asia and may account for the high incidence of the malignancy.

Pathologic Findings

Interesting pathologic findings have emerged recently. Electron microscopic studies of gestational and nongestational choriocarcinoma have found them virtually identical in every respect.³⁷ Also normal pregnancy, mole, and choriocarcinoma all have identical trophoblastic patterns as seen under the electron microscope. During these studies it was found that human chorionic gonadotropin was produced by the syntro-

phoblast, not by the cytotrophoblast,³⁸ and that the syncytium is derived from cytotrophoblast.³⁹ Sex chromatin of choriocarcinoma may be either male or female, regardless of which sex harbors the tumor.²⁸

Chorionic Gonadotropin or Pituitary Gonadotropin

The possibility exists that human chorionic gonadotropin may differ from pituitary gonadotropin. Schwartz and Mantel⁴⁰ in experiments with rabbit antisera could not account for 20% of the human chorionic gonadotropin. They postulated that it was an immunologic variant not present in pituitary gonadotropin, but they could not identify it. However, the bulk of evidence⁴¹ seems to indicate that the gonadotropins from the two sources are identical, both immunologically and biologically.⁴² Human chorionic gonadotropin from normal and molar pregnancies may be identical except for minor antigenic differences.⁴³ Further refinements of technique may allow their differentiation in the future. Chorionic gonadotropin of normal pregnancy contains a fraction of biologically active hormone and a smaller fraction of biologically inactive, immunologically active hormone. The ratio is reversed in trophoblastic disease,⁴⁴ a fact that could be the basis for a diagnostic test. The primary biologic activity of human chorionic gonadotropin seems to be from luteinizing hormone which, of course, is responsible for the compound lutein cysts seen with trophoblastic tumors. Why these cysts occasionally appear after a mole has been evacuated remains unanswered. Perhaps the pituitary "rebounds" after being suppressed by human chorionic gonadotropin. Molar gonadotropin may have altered activity, because it has been shown that estrogen levels are usually normal in that disease.⁴⁵

Conclusions

The concept of trophoblastic disease is confusing, even to the initiated. To complicate the clinical management, common diagnostic criteria are not shared by investigators. Consequently, evaluation of

Continued

current treatment, especially chemotherapy, is difficult. In the future, new diagnostic tests for the gestational trophoblastic

tumors will evolve, probably from the field of immunology. From that field also, additional modes of treatment probably will be derived.

Gulliver on Diseases and Doctors

"It would be endless to give a catalogue of all diseases incident to human bodies; for they could not be fewer than five or six hundred, spread over every limb, and joint: in short, every part, external and intestine, having diseases appropriated to each. To remedy which, there was a sort of people bred up among us, in the profession or pretence of curing the sick . . . Their fundamental is, that all diseases arise from repletion; from whence they conclude, that a great evacuation of the body is necessary, either through the natural passage, or upwards at the mouth . . . But, besides real diseases, we are subject to many that are only imaginary, for which the physicians have invented imaginary cures; these have their several names, and so have the drugs that are proper for them.

"One great excellency in this tribe is their skill at prognosticks, wherein they seldom fail; their predictions in real diseases, when they rise to any degree of malignity, generally portend death, which is always in their power, when recovery is not: and therefore, upon any unexpected signs of amendment, after they have pronounced their sentence, rather than be accused as false prophets, they know how to approve their sagacity to the world by a seasonable dose."

Clinical Path Conference

Fever, Hemolytic Anemia, and Uremia

THIS 58-year-old white construction worker was first admitted to St. Barnabas Hospital on May 11, 1965, to evaluate his weight loss. He had developed severe diarrhea one year previously and had had several exacerbations with up to six to eight stools a day. His weight had decreased about 25 to 30 pounds during this period, but he had gained 10 pounds after the diarrhea subsided. He had been a known diabetic for six years, maintained on tolbutamide rather than insulin, and had experienced urinary frequency and increased thirst for six months. Although he tested his urine only infrequently, it always showed sugar.

He appeared older than his stated age and had a blood pressure of 170/110 and a normal temperature and pulse. No masses were felt. The lungs and heart were normal; he had reduced reflexes. His blood sugar was 200 mg./100 ml., cholesterol 200 mg./100 ml., and PBI 2.6 mcg. He was treated with insulin and discharged on 25 units, a diabetic diet, and a thyroid preparation.

He was re-admitted two weeks later with chills and night sweats. He had no diarrhea and felt well until his night chills started. Five days before admission, he had become confused, febrile and weak, and had again developed diarrhea. When seen at his local hospital, he had a blood sugar of 300 mg. per cent and was treated with 40 units of insulin. His sensorium fluctuated from clear to confused. Before transfer to Minneapolis his mind was clear, but on arrival he was confused, incontinent, and in a shock-like state.

On examination he was confused and had irregular respiration. The blood pressure was 90/50, and the temperature was 102° F. The examiner could not feel the spleen or liver. The patient's wife said he had worked as a foreman of a construction crew in Africa in April of 1965.

Laboratory data included a hemoglobin of 7.3 Gm. per cent, a wbc. of 9,850, and a differential of 8 polymorphonuclear leukocytes, 42 band forms, 4 myelocytes, 5 monocytes, 38 lymphocytes, and 3 plasma cells. The smear showed 5 normoblasts/100 wbc. The urinary sediment revealed a trace of albumin, 3+ sugar, 2 to 6 hyaline and 6 to 15 granular casts/lpf, and 0 to 2 wbc/hpf. Initially, his urine sediment showed no red cells, but on two later occasions 20-30 RBC/hpf. were seen. The urine was hematest negative. Chemical tests included glucose of 240 mg./100 ml., blood urea nitrogen of 35 mg./100 ml., sodium of 130 mEq/l, a chloride of 98 mEq/l, potassium of 4.2 mEq/l, carbon dioxide combining power of 13 mEq/l, creatine clearance of 25 cc./minute, a protein-bound iodine of 2.6 mcg. and a cholesterol of 200 mg./100 ml. The sequential acid base studies are shown in Figure 1. The urine culture disclosed about 5000 colonies of *Escherichia coli*.

After four to five days the patient began to void 3500 cc. of urine a day. His fever returned, and his hemoglobin fell in spite of eight transfusions. The creatinine clearance two weeks after admission was 25 cc./min. and five days later was 11 cc./min. The BUN at this time was 95 and increased to 120. His urine output varied from 3000 to 3500 cc./day. He was given increased fluid, but he continued to sweat profusely and remained confused. His polyuria subsided and the BUN declined to 45 in six weeks. Then he again became febrile, his hemoglobin fell, and his BUN increased to 65. A fluctuant mass developed in his buttocks, which was incised, yielding *Staphylococcus aureus*. Again he improved and was discharged 10 weeks after admission.

Continued

CLINICAL PATH CONFERENCE

He was re-admitted in late August with chills and slight fever. In the intervening time he had been well, alert, and in good diabetic control. His BUN was 42 and his hemoglobin 11 mg. per cent after transfusions.

He was again re-admitted in October 1965 for recheck and brought in a small firm tissue-like fragment he had passed in his urine, stating that he had passed a similar fragment one week previously but was unable to retrieve it. Culture of urine again revealed *E. coli*. BUN was 39 mg./100 ml., FS 135 mg./ml., and wbc. 13,000.

He was examined for the last time in May, 1966, when he had peripheral edema, had gained ten pounds in weight, and complained of dyspnea. The heart size was increased. Creatinine was 3.4 mg./100 ml.; hemoglobin, 12.1 Gm. per cent; specific gravity of the urine, 1.007. Urine culture was negative and wbc. 10,700. He was given diuretics, improved, and was discharged.

Discussion

Dr. Dennis Kane:*

This 58-year-old white man was first admitted in May, 1965, to evaluate his weight loss. Before that he had had diarrhea for about one year with six to eight stools a day. Did his doctors perform either stool cultures or proctoscopy?

Dr. Wayne A. Chadbourn:** Not so far as we know.

Dr. Kane:

I have to consider bacterial diarrhea or ulcerative colitis in a man with his travel history. A patient who had been to Africa and who has diarrhea should have had a proctoscopy, and his stool should have been studied for ova and parasites. He was denied the benefit of these studies; but we must persevere and continue to follow him as he gets into more trouble.

He then proceeded to lose from 25 to 30 pounds. This is an alarming symptom, particularly when the weight loss is not purposeful. Do we have a baseline weight on him?

Dr. Chadbourn: His weight decreased from 175 pounds to 150 pounds.

Diabetes

Dr. Kane:

A 25-pound weight loss in William Howard Taft would be hardly detectable, but in Calvin Coolidge it would alarm us. Now, let's get the meat of his problems. When the patient was 52, his doctor diagnosed diabetes mellitus, presumably postmaturity-onset diabetes. These diabetics are often overweight and can be maintained on tolbutamides. This patient's diabetes was controlled for six years on such a regimen without insulin.

Then he showed the classic triad of diabetes with polyuria, polydipsia and weight loss. He checked his urines and was constantly spilling sugar, which could mean an alteration of his metabolism of glucose or an exacerbation of his diabetes. The most common cause of the latter is infection, and I assume he had a kidney infection.

When he was examined, he looked older than he was. Premature aging is typical of diabetes. He was hypertensive with a high diastolic pressure which indicates that he had developed trouble in one of the target organs of diabetes — the kidney. Pyelonephritis is an exceedingly common disease in diabetics, and it is a common sequel of longstanding diabetes.

*Attending Internist, St. Barnabas Hospital.

**Pathologist, St. Barnabas Hospital.

Laboratory Data

At 200 mg./100 ml. the blood sugar was elevated but not startlingly so. Now we come to a paradoxical bit of information. His cholesterol was 200 mg./100 ml., and his PBI (protein bound iodine) was 2.6 mcg. per cent. I have never seen a patient with hypothyroidism with this low a cholesterol. Furthermore, it is unusual indeed for an individual with myxedema to have a serum cholesterol in the low normal range. How can we account for a low cholesterol and low PBI? Mercurial diuretics can lower the PBI, since they precipitate iodine and thus artificially lower the PBI. Did he receive any mercurials?

Fig. 1 — A "metabolic map" of the patient's acid-base status. The pH's and CO₂ contents were performed on venous blood. The first determinations indicate metabolic acidosis; later values show a return to normal. The normal region is the central hexagonal area.

Continued

Dr. Chadbourn: He was given no mercurial diuretics.

Dr. Kane:

The nephrotic syndrome reduces the PBI. Here the mechanism for lowering the PBI is related to loss of iodine-carrying compound protein into the urine. Nothing in the protocol indicates that he was spilling protein, and his physicians did not treat him for the nephrotic syndrome.

Discharge and Readmission

His physician treated him with thyroid and insulin and discharged him. He was readmitted two weeks later with chills and night sweats. He had felt well until his night chills started. Five days before admission he had become confused, afebrile and weak and had developed diarrhea again. His chest x-rays showed a rapid onset of pulmonary edema with fluid in the left pleural space.

Congestive heart failure, particularly right heart failure, in a patient with no previous cardiac difficulties deserves comment, but first I will try to explain the chills and fever. This patient had an acute process with chills, night sweats, then confusion. His fever, weakness, and the flare-up of the diarrhea indicate a pansystemic disease.

"Shock-Like" State

He was first seen at his local hospital with a blood sugar of 300 which I interpret as a reaction to infection and indication of increased glycolysis.* He was treated with 40 units of insulin. His diabetes at that particular time was not life-threatening, but he was said to be in a "shock-like" state, which is a euphemism for shock.

This patient was in shock. His blood pressure was 90/50; he was not perfusing his brain; his respirations were irregular; and his temperature was elevated. His neurological examination was normal. He had no localizing signs of pyramidal tract involvement, of cerebral hemorrhage, or of extradural bleeding.

Hemolysis

Now we come either to the crux of the protocol or to a large "red herring." His wife recounts that he worked as a foreman of a construction crew and had had three jobs in Africa in recent years. He was last in Africa one month before he was admitted. Where was he in Africa?

Dr. Chadbourn:

Two of the jobs were in Central-Africa. The last was in Kenya.

Dr. Kane:

Now that we know where he was in Africa, let's look at his laboratory data, some of which is striking. His hemoglobin was 7.3 Gm. per cent, his wbc. was mildly elevated, and his urine culture showed *E-Coli*. In the absence of frank bleeding, this man lost half his red-cell volume. I conclude that he was hemolyzing his red cells. Was a reticulocyte count, fecal urobilinogen, or bone marrow done?

*See Test Your Word Score Page 63.

Dr. Chadbourn:

His reticulocyte count was 4.6%. The other studies were not done.

Dr. Kane:

Hemolytic anemias usually, but not always, have a reticulocyte count much higher than 4.6%. Sometimes pernicious anemia treated with B-12 will respond with a reticulocytosis of similar range as hemolytic process. But he had no stigmata of pernicious anemia, and I think he had hemolysis. His hemolysis was associated with fever. His fever continued, and his hemoglobin kept declining despite blood replacement. Again no mention was made of bleeding.

Renal Failure and Heart Failure

We now go on to find out that he had creatinine clearance two weeks after admission of 25 cc./minute. Five days later it fell to less than half of that. The endogenous creatinine clearance is essentially the same as the inulin clearance. It is a measure of glomerular filtration rate and is usually constant and unaffected by protein metabolism or urine volume.

I suspect a lower nephron nephrosis developed in this patient. His kidneys were probably overloaded with red cells, his tubules may have been plugged with hemoglobin casts, and because of heart failure he was perfusing his renal tissue poorly. He may have gone into hyperkinetic failure because of sudden anemia. Only a limited number of conditions produce hyperkinetic, or high output, or hyperdynamic failure. In this condition a disparity exists between the venous pressure and the circulation time. We see it in shunting diseases like left to right shunts, large pulmonary arteriovenous anastomosis, telangiectatic diseases, and cirrhosis. It occurs in portal cirrhosis when there is a shunting between the systemic and portal circulations. One sees it in Paget's disease* when shunts develop in bone. One sees it in thyrotoxicosis. No venous pressure or circulation time is recorded for this patient.

But the patient had none of these diseases, and the logical cause of his heart failure was severe anemia. Renal failure complicates the interpretation of his anemia. His rapidly mounting nitrogen retention would depress the bone marrow and suppress the synthesis of myeloid and erythroid cells.

Now let us consider his renal failure. His ability to concentrate was lost. According to the protocol his specific gravity was 1.007. His physicians increased his fluid intake to overcome dehydration, but the patient remained confused, and he sweated profusely. This information is important because patients with uremia usually sweat poorly. When you see an ambulatory sallow patient who does not sweat, order a BUN. Frost often develops in these patients in the place of perspiration. I wonder, therefore, if this patient had true azotemia. His clinical course affirms my impression. His BUN came down to 45 in six weeks, and his output increased. In acute renal failure, the BUN may go in a few days from 10 up to 180 mg. per cent. This may occur with incompatible blood transfusion or crush syndrome. When the cause is reversed, the BUN falls as much as 50 mgm./100 ml. per day. Once it reaches about 45 mg./100 ml. it drifts slowly towards normal. When the BUN is in the 40s it can still exert a toxic

*See Page 113.

Continued

influence on the bone marrow, and the patient may continue to have marrow depression. As this patient's BUN came down, his hemoglobin went up. Then his fever returned, his hemoglobin dropped, and his BUN climbed.

I think he was following the pattern of a lower nephron nephrosis, triggered by an overload of hemoglobin from hemolysis. The creatinine is a good index of the tubular efficiency. Usually if you multiply the creatinine by 10, you can get a rough estimate of the BUN. But this rule doesn't hold in this patient, and I can't explain the discrepancy.

What else could have given the picture of lower nephron nephrosis? Hypokalemia can produce tubular lesions with an azotemia, but this patient's serum potassium values, which may not reflect his total body potassium, do not justify the diagnosis of hypokalemic nephropathy.

Diabetes and the Kidney

Diabetes could have contributed to the uremic picture. When he was admitted again in October of 1965, he brought with him a small tissue-like fragment that he passed in his urine and said that he had passed a similar fragment one week before. Renal papillary necrosis is a fairly frequent complication of diabetes, and he may have sloughed off a papilla. Papillary necrosis can lead to uremia with and without acidosis. Radiologists can identify papillary necrosis because they see serrations or irregularities on the pyelogram. This patient probably had a pyelonephritis with focal papillary necrosis.

In May of 1966 he showed peripheral edema. Edema could result from hypoalbuminemia secondary to the Kimmelstiel-Wilson syndrome. But patients with this syndrome frequently present with a heavy proteinuria, and their urinary sediment is filled with hyaline and granular casts and doubly refractile fat bodies. Also, the heavy loss of protein results in a nephrotic syndrome with hypoalbuminemia and hypercholesterolemia. He had neither the blood nor the urine changes, and I will discard the diagnosis of Kimmelstiel-Wilson's disease.

Fig. 2

Fig. 3

Fig. 4

Fig. 2, 3, and 4 — Figures 2 and 3 are peripheral blood smears showing typical ring forms of *P. falciparum*. Figure 3 also demonstrates a "crescent" form of the parasite. Figure 4 is a high power view (430 $\times$) of the necrotic renal papilla which the patient passed in his urine.

Conclusions

Now it remains to tie this all together in this 58-year-old diabetic with a multi-system disease characterized by fever, hemolysis, and uremia. I can best explain it by going back to Central-Africa. I think that in addition to his diabetes he had a lower nephron necrosis probably caused by hemolysis from *P. Falciparum* malaria. I mention *P. Falciparum* because it has more frequent relapses than malaria caused by other species and is more chronic. It can produce chills, fever, dark urine, and rapidly developing anemia. In conclusion then, I feel this patient with post-maturity-onset diabetes contracted a *Plasmodium Falciparum* malaria; that he then had an *E.-Coli* pyelonephritis; that his malaria recurred associated with massive hemolysis, right heart failure, and lower nephron nephrosis; and that he then had an episode of renal papillary necrosis. One of the penalties for his hospitalization was bilateral staphylococcal abscesses of the buttocks from injections.

Dr. Dennis Kane's Diagnosis

1. *Plasmodium Falciparum* malaria with hemolysis and lower nephron nephrosis.
2. Diabetes mellitus.
3. Pyelonephritis (*E-Coli*) with renal papillary necrosis.

Pathological Diagnosis

Dr. Chadbourn:

Dr. Kane's diagnoses are correct. When this patient was admitted we were alarmed by the massive hemolysis and shock. An overwhelming bacterial infection in hemolysis entered our minds, but we did not think of malaria. However, we quickly made the diagnosis on a peripheral smear. We saw the characteristic ring forms of *P. Falciparum*, or estivoautumnal malaria (Figures 2, 3). His blood showed the effects of hemolysis with nucleated red cells, basophilia, and reticulocytosis. Although he had most of the hallmarks of Blackwater fever — rigor, fever, intravascular hemolysis, collapse, renal failure, and uremia — he never passed black water. Usually these patients have a low nephron nephrosis with necrosis of tubules, hemoglobin casts, and hemoglobinuria. We do not have a kidney biopsy, and I could only speculate on the cause of his uremia. As Dr. Kane predicted, he did pass a necrotic papilla later (Figure 4). Most diabetics with renal papillary necrosis run a fulminating course with uremia and death. We cannot elicit a history of phenacetin ingestion in this patient — the other common cause of papillary necrosis — and we assume he sloughed his papillae because of his diabetes and superimposed pyelonephritis.

Anatomical Diagnosis

1. Estivoautumnal malaria (*P. Falciparum*) with hemolysis.
2. Necrotic renal papillae.

Men usually get somewhere when they develop a brake for the tongue and an accelerator for the brain. — Gas Flame

Breast cancer can be highly curable if it is detected early, through regular examinations. Yet, despite all efforts in cancer education and improvements in treatment techniques in the last 30 years,

**THE NUMBER OF
BREAST CANCER DEATHS
PER 100,000 WOMEN
IN THIS COUNTRY
HAS NOT DECLINED.**

While research continues to seek new answers, it is imperative that greater efforts be made to detect breast cancer early and to get women to their doctors when chances of cure are best. That's why the American Cancer Society is encouraging its Divisions across the country to carry out special breast cancer educational programs. Newest of these are demonstration projects in which physicians in a community volunteer one day to giving breast examinations and to teaching hundreds of women breast self-examination. Breast cancer is one of the major cancer problems which we face and which together, doctor, we must try to resolve through intensified research and educational efforts.

AMERICAN CANCER SOCIETY

Grand Rounds

*Thyroid Storm**

JEAN R. ECKERLY, M.D.
Instructor in Medicine

"Let it not be said of the patient with masked hyperthyroidism that it was the physician who wore the mask." — Unknown

Clinical Picture

Thyroid crisis, or "storm," has been defined as a severe exacerbation of hyperthyroidism, characterized by tachycardia, increased pulse pressure, tremor, nausea, vomiting and diarrhea with dehydration, and delirium or coma. However, it is fever which appears to separate "storm" from severe thyrotoxicosis.

The temperature may rise rapidly, and it was once thought that it should reach 103 degrees F. for the diagnosis to be secure.¹ However, a recent report of 21 episodes of thyroid "storm" indicates that a fever of 100 degrees F. or greater is a cardinal sign since it is not seen in uncomplicated thyrotoxicosis.³

Marked tachycardia is characteristic, with pulse rates ranging from 100 to 170 per minute and occasionally greater, but usually around 140 per minute.² The pulse pressure is similar to that seen in thyrotoxicosis, between 60 and 100 mm. mercury. Congestive failure may ensue.

Abdominal pain may be a prominent feature⁴ and, when accompanied by vomiting and diarrhea, is considered an ominous sign.⁵

Probably the most striking feature of "storm" is the appearance of the patient, who may present with a variety of mental and emotional disturbances. These will range from asthenia and coma to extreme restlessness and emotional lability. The tremor may be so marked as to simulate seizure-like activity and will include the face, body and eyes. Patients

in "storm" have been hospitalized on psychiatric wards as hallucinatory schizophrenics.²

Thyroid crisis is most common in patients with Grave's disease,⁴ but a variety of thyroid abnormalities which will produce hyperthyroidism have led to "storm."^{2,6} See Table 1.

The major complication of thyroid storm is death, although acute renal tubular necrosis has been reported.⁷

Incidence and Mortality

In past years thyroid storm was seen in about 10% of patients who underwent surgery for a toxic goiter⁸ and accounted for 75% of the deaths associated with thyroid surgery.⁹ Mortality from "storm," once 50 to 100%, is still between 20% and 30%.² However, the incidence of storm has dropped so that single cases are now reported in the literature.

Precipitating Factors

"Escape" from iodine preparation and thyroid surgery no longer play an important etiologic role in "storm." It has now become evident that a large variety of stressful situations, such as listed in Table 2, can precipitate storm. Surgical procedures on the unsuspected or mildly hyper-

THYROID STORM

thyroid patient are notable as precipitating events.¹⁰ Because of the difficulty in diagnosis of hyperthyroidism in pregnancy, "storm" occurring at the time of delivery can be a perplexing diagnostic problem.^{11,12}

Pathophysiology

Large amounts of circulating thyroid hormone as the cause of post-thyroidectomy storm seems to be supported by reports of "storm" due to exogenous thyroid poisoning.¹³ However, reports of PBI's and iodine uptakes during storm are not significantly different from those seen in uncomplicated thyrotoxicosis.¹⁴⁻¹⁶ If these cases represent relative thyroid poisoning, then one or more permissive or inhibitive factors must be involved.

There is a large volume of data in support of the theory that epinephrine is responsible for the clinical manifestations of thyrotoxicosis. Hyperthyroid individuals are sensitive to and react more vigorously to the stimulatory effects of catecholamines,^{4,17-19} and the effects of thyroid hormone can be abolished by sympathetic blockade.²⁰ Epinephrine levels have been reported elevated²¹ as well as normal in these patients.¹⁷ Perhaps these observations can be explained by the evidence that hyperthyroids have a decreased ability to catabolize catecholamines, which leads to prolongation of action and accumulation in tissues.²² This, coupled with the observation that thyroxine potentiates the calorogenic effect of epinephrine,²³ has led to the hypothesis that thyroid storm is due to an adrenergic outburst.²⁴ Direct evidence that this is indeed an absolute increase of catecholamines is entirely lacking.

The thyrotoxic patient has also been shown to have rapid clearance of hydrocortisone from the blood,²⁵ and further studies have shown these patients to have relative adrenal insufficiency as defined by a three-day ACTH test.²⁶

Current knowledge about the direct effects of thyroid hormone would place the site of action in the mitochondria where it has been observed to selectively inhibit oxidative phosphorylation,* inhibit certain pyridine nucleotide dehydrogenases, and activate the membrane structure.^{4,27}

Stress, in the relatively adrenal-insufficient hyperthyroid individual, seems to be a factor in the production of thyroid storm, but its exact role is unknown. Storm has been thought of as "decompensated thyrotoxicosis,"⁸ somewhat analogous to ketoacidosis in the diabetic,²⁷ wherein oxidative phosphorylation becomes completely uncoupled and the picture of adrenergic outburst is seen.²⁸ Theoretically, the degree of stress required to produce "storm" should be inversely proportional to the degree of thyrotoxicosis.²⁹

Diagnosis

The diagnosis of storm is made entirely on clinical grounds and usually presents little problem in the known hyperthyroid. Some difficulty may obviously arise in the hyperthyroid with an infection; however, with the knowledge that storm may be precipitated, prophylactic therapy is indicated.

It is the undiscovered or unsuspected hyperthyroid patient who may develop storm under conditions of stress that presents the difficult diag-

*Test Your Word Score Page 63.

Continued

nostic problem. Storm may be confused with infection, CNS disorders and acute enterocolitis. Just how rapidly a patient may develop thyrotoxicosis and progress to storm is unknown, since retrospective analysis of a case may yield subtle clues of hyperthyroidism. However, patients who storm within two months of the onset of their thyroid disease have a very poor prognosis.²

The problem then is when to suspect the presence of hyperthyroidism. Table 3 lists some of the usual findings of the disease and the frequency with which they appear. Any one of the signs of mild hyperthyroidism such as nervousness, diarrhea, muscular weakness and tremor of the hands may be the only clue. The disease should be ruled out in any patient who is being diagnosed as having hypertensive cardiovascular disease, cardiac decompensation, chronic ethanolism,* occult or gastrointestinal cancer, chronic ulcerative colitis, sprue, pheochromocytoma, myasthenia gravis or psychoneurosis. The frequency with which the diagnosis of mild hyperthyroidism is made must necessarily be proportional to the height of the clinician's index of suspicion.

Treatment

The treatment of thyroid storm is aimed at these three known parameters: excess thyroid hormone, increased adrenergic activity, and probable relative adrenal insufficiency.

Iodide, which inhibits the release of thyroxine and tri-iodothyronine from the stored thyroglobulin is given as sodium iodide intravenously in a dose of one to three grams daily^{2,4} or as Lugol's solution 30 to 60 drops daily.

Propylthiouracil, which blocks oxidation of iodide to iodine, is given in a dose of 600 to 1,000 mgm. daily² (methimazole 60 to 100 mgm. daily may be used).

*See Test Your Word Score Page 63.

THYROID STORM

With iodide alone, mortality of 75% or more was still observed. Addition of thioureas* dropped mortality rates to 40% and the addition of reserpine dropped them a bit more.²

Reserpine, given for its sympatholytic effect, is used as a dose of one to three mgm. intramuscularly every six to eight hours to control restlessness and tachycardia (Guanethedine, 20 to 50 mgm. every eight hours may be used).

The most dramatic decrease in mortality is seen with steroid administration and this has now become a routine part of therapy. Usual doses are 40 to 60 mgm. of prednisone or its equivalent daily³⁰ during the period of storm and then rapidly tapered.

This combination of therapy should bring about a dramatic response in two to four days.² The patient should be kept on suppressive therapy until the clinical condition allows definitive treatment.

Prophylactic treatment of the hyperthyroid patient is obviously the most desirable form of therapy.

Case Report

A 50-year-old, white, married female was transferred to this hospital on 6/10/66 with a chief complaint of nausea, shortness of breath, abdominal swelling and lower abdominal discomfort.

She dated her present illness to March, 1966, when she had a 10-day episode of nausea and vomiting unaccompanied by other gastrointestinal symptoms. She was seen by a physician shortly afterward for shortness of breath and ankle swelling. She was given digitalis and diuretics and had a 20-pound weight loss.

On 5/30/66 she was admitted to another hospital with urgency, frequency, and dysuria. Physical examination revealed blood pressure to be 160/70, pulse rate 90 and a large lower abdominal mass. Laboratory data included a BUN of 220 mgm. %, CO₂ 10 mEq/l, chloride 79 mEq/l, potassium 4.6 mEq/l, sodium 129 mEq/l and hemoglobin 8.5 gm. %. Retrograde pyelography revealed bilateral ureterectasis. Ureteral catheterization produced a good urine output and she was transferred to Hennepin County General Hospital for definitive treatment.

Physical examination on admission to Hennepin County General Hospital revealed an ill-appearing woman who was moderately short of breath. Blood pressure was 180/90, pulse rate 88, temperature 98.6 degrees. Positive physical findings were palpable thyroid with a 1 to 2-cm. nodule in the midline (re-evaluation shows this to be a multinodular thyroid, right lobe, larger than the left, estimated at 40 grams). Aortic systolic ejection murmur, nodular tumor mass in the pelvis and moderate peripheral edema were present.

Laboratory data revealed hemoglobin to be 7.1 gm.%, wbc. 11,200 with 95% PMN's, urinalysis 175 to 200 RBC/NPF (ureteral catheters in place), 3+ albumin, 3+ sugar; VDRL negative; ESR 109; BUN 147, creatinine 7.5, calcium 10.4, PO₄ 7.6, Na 131, K 5.6, CO₂ 11, chloride 114 and FBS 121 mgm. %.

Hospital Course: The patient was put into electrolyte balance by peritoneal dialysis, and exploratory laparotomy was performed on the fourth hospital day. A large myomatous uterus was removed. Following surgery urine output improved markedly. However, immediately postoperatively the patient was noted to be febrile (T. 102.4 degrees) with a pulse of 108 and blood pressure 170/70, and she remained moderately febrile with a tachycardia of around 110/min. until the fourth postoperative day when she was noted to have rapid eye movements, marked twitching of extremities and mental confusion. She remained confused and on the sixth postoperative day developed a fever of 103 degrees F., with pulse 120, accompanied by diarrhea. Blood cultures, spinal fluid, sputum and stool cultures were negative. Proteus was found in the urine and the patient was treated with chloromycetin and vancomycin with little clinical response. Hypocalcemia and hypomagnesemia were suspected and treated, but laboratory values failed to support these diagnoses and the patient's condition remained unchanged. On the eighth postoperative day she was started on Solucortef, 300 mgm/day, Na iodide, 1.5 gm/day, propylthiouracil, 800 mgm/day, and reserpine, 1.5 mgm. I.M. q. 6 hours. Within four days the pulse rate was down to 80 per minute and the

*See Test Your Word Score Page 63.

Continued

GRAND ROUNDS

temperature normal. ET-3 on the day therapy was instituted was 20.6%. Total thyroxine drawn after the patient had responded to therapy was 5.58%.

The patient is currently under control with propylthiouracil which is being tapered to allow thyroid function studies to be done. She has continued to show evidence of renal failure requiring dialysis, which has been done without incident.

Diagnoses: 1. Renal failure secondary to obstructive uropathy from myomatous uterus.

2. Thyroid storm secondary to toxic nodular goiter.

Speaking of Operations

Until I passed through the experience of being operated on myself, I never really realized what a precious conversational boon the subject is, and how great a part it plays in our intercourse with our fellow beings on this planet. To the teller it is enormously interesting, for he is not only the hero of the tale but the rest of the cast and the stage setting as well — the whole show, as they say; and if the listener has had a similar experience — and who is there among us in these days that has not taken a nap 'neath the shade of the old ether cone? — it acquires a double value. "Speaking of operations —" you say, just like that, even though nobody present has spoken of them; and then you are off, with your new acquaintance sitting on the edge of his chair, or hers as the case may be and so frequently is, with hands clutched in polite but painful restraint, gills working up and down with impatience, eyes brightened with desire, tongue hung in the middle, waiting for you to pause to catch your breath, so that he or she may break in with a few personal recollections along the same line. From a mere conversation it resolves itself into a symptom symposium, and a perfectly splendid time is had by all. — Irvin S. Cobb: *Speaking of Operations*.

A Religious Practice

If you have operated conscientiously on the rich for a proper fee and on the poor for charity, you need not play the monk, nor make pilgrimages for your soul. — Henri de Mondeville (c. 1260-1320)

Lacerations of Hand Tendons

Current Concepts of Treatment

HAMLET A. PETERSON, M.D.*
PAUL R. LIPSCOMB, M.D.**
Rochester, Minnesota

ALTHOUGH LOWEST on the scale of tissue priorities, tendon injuries challenge surgical judgment and skill as much as if not more than do injuries of any other tissue. To join the ends of a severed tendon by surgical suture is easy, but to obtain a normal gliding structure is difficult.

Anatomic Considerations

In most areas of the hand, the tendon is surrounded by paratenon which is areolar tissue filling the interstices of the fascial compartment in which the tendon is situated. Some tendons, in certain sites where they might rub against bone or other friction-generating surfaces, are enclosed in sheaths. Embryologically this sheath is the invagination of a mesenchymal cleft which has undergone synovial differentiation during the second month of fetal life. For practical purposes, this invagination produces two sheaths. The outer one is a connective tissue tube, called the "fibrous" or "parietal sheath," with its exterior attached to the structures that surround it. The inner, visceral sheath directly encloses the tendon, is firmly attached to it, and is called the "epitenon." The mesenterylike double fold of synovial membrane connecting the two sheaths is called the "mesotenon." The space between the epitenon and the fibrous sheath contains synovial fluid which is an excellent lubricant.

Preservation of blood supply to the tendons comprises the key to the management of tendon injuries.¹ Despite the extremely

low metabolic requirements and extremely low respiratory rate of tendon, its survival depends on an adequate blood supply, rather than on diffusion of gases and nutrients from surrounding tissues. In the hand, specific architectural needs of different areas modify the blood supply. Tendons with paratenon receive blood vessels from all sides and therefore heal rapidly. Those tendons invested in sheaths derive their blood supply from the mesotenon, all branches originating in the bed deep to the tendon. From this bed they pass into the mesotenon, branch into arcades of vessels, and enter the tendon. Each arcade has some anastomotic connection with the ones lying on either side of it, but primarily it nourishes a small localized segment of tendon. Blood supply to any single segment will not support circulation in adjacent segments more than 1 or 2 cm. long; as a result, large portions of any tendon freed at operation must function as free tendon grafts until a blood supply is restored by the ingrowth of vessels. In the finger this mesotenon is reduced to two vincula, the longus and the brevis, carrying the vessels (Figure 1).

In the hand, tendon sheaths extend proximally from the insertion of the flexor superficialis on the middle phalanx to their termination at a level just proximal to the metacarpophalangeal joints in the palm. Externally this area is from the middle of the middle phalanx proximally to the distal palmar crease. The flexor sheath of the thumb extends from the terminal phalanx to a point 2 or 3 cm. superior to the proximal volar crease of the wrist. Wherever a

Continued

tendon spans the concavity of a joint, a pulley mechanism is necessary to prevent "bowstringing." These pulleys, the annular ligaments, are thickened, tough parts of the fibrous sheath and are between joints, not opposite them.

Tendon Healing

Tendons are not inert structures, even though their metabolism is low, and they respond to physiologic stress by hypertrophy. Disuse results in atrophy and degeneration. When lacerated, tendon ends become edematous and proliferate. If not coapted* exactly, these ends adhere to surrounding injured tissue, a tendency which makes it essential not only that the ends be carefully coapted but that no unopposed fibers are left free. Many techniques of tendon suture have been devised. The site of repair should be kept well away from the skin incision if possible.

Suture Material and Technique

Catgut is unsatisfactory for tendon suture because of the possibility of infection after tissue rejection. Silk occasionally causes a reaction, although modern, untreated silk is less likely to do so. Stainless steel wire provokes the least reaction; it glides easily and is strong for its diameter. Kinks in the wire weaken it and should be avoided. Monofilament, 34-gauge wire is apparently the most popular for tendon-to-bone suture, while multistrand wire is gaining in popularity for tendon-to-tendon suture. Monofilament wire can be placed in such a way

that it can be removed when tendon healing is complete (Figure 2-a). This is particularly important where tendons glide in sheaths or lie near a joint or just beneath the skin.

Further exposure of the tendon to be sutured may be necessary. Additional incisions should be made without crossing flexion creases at a right angle. Less exposure is needed distally than proximally since there is no muscle pull on the distal tendon ends and since passive flexion of the fingers will deliver the distal ends into the wound.

In suturing tendons, handling should be delicate, to minimize reaction and scarring as much as possible. The tendon ends must be accurately opposed and the gliding surface must be free of blemish. All crushed parts should be removed after the sutures are secured.

Repair of Extensor Tendons

Extensor tendons of the hand can usually be repaired primarily at almost any level in clean incised wounds if skin coverage is adequate^{3,4} (Figure 3). The paratenon of extensor tendons ensures a good blood supply for healing. Even without suture the extensor tendons often unite with bridges of scar tissue and, because they are surrounded by the loose areolar tissue, are able to glide and function satisfactorily.

In contrast to flexor tendons, excursions of the extensors are shorter and their motions are weaker, placing less stress at the repair site. However, certain anatomic features call for great care and exacting tech-

Fig. 1 — Blood supply to tendons in digital sheath. (A) = vincula brevis; (B) = vincula longus; and (C) = mesotenon connecting superficialis and profundus. (Modified from Smith, J. W.: Blood Supply of Tendons. *Amer J Surg* 109:272, 1965.)¹

*See Test Your Word Score Page 63.

nique in repair or replacement. Extensor tendons in the fingers and thumb are extremely thin, form a part of the joint capsule, and lie in close proximity to bone and skin. The complex relationship existing be-

tween extensor tendons and the intrinsic mechanism must be preserved.^{3,5,7}

Mallet Finger

Primary repair is indicated in lacerations

Fig. 2 — Common suture techniques. (a) Bunnell pullout suture; (b) double right-angle suture; (c) figure-of-eight suture; (d) Verdan's transfixion technique. (Modified from Peacock, E. E., Jr.: *Practical Joints in Repair of Injured Tendons*. Hosp Med October, 1965, p. 28.)²

Fig. 3 — Extensor tendon repair. (Modified from Holm, C. L., and Embick, R. P.: *Anatomical Considerations in the Primary Treatment of Tendon Injuries of the Hand*. J Bone Joint Surg 41-A:599, 1959;⁵ Kelly, A. P., Jr.: *Primary Tendon Repairs: A Study of 789 Consecutive Tendon Severances*. J Bone Joint Surg 41-A:581, 1959.⁶)

Continued

of the conjoined tendon. Immobilization in extension is most satisfactorily obtained with a Kirschner wire across the distal joint or with a plastic or aluminum splint. Severe, untreated mallet-finger deformity may lead to hyperextension of the proximal interphalangeal joint because of unopposed pull of the central slip.

Boutonnière Deformity

Lacerations in the region of the middle joint may involve the extensor slip to the middle phalanx, causing a so-called button-hole or boutonnière deformity which may not be immediately recognizable. This deformity consists of flexion of the middle joint and extension of the distal joint because of volar displacement of the lateral bands. Therefore, this particular region should be carefully explored during primary wound repair and the central slip restored if possible. Failing this, the lateral bands should be approximated on the dorsum of the finger and sutured together to prevent volar displacement. Immobilization of the finger in extension is required.

Extensor Hood and Dorsum of Hand

Injuries to the extensor hood, including

the lateral expansions with intrinsic insertions, must be carefully sutured. The long extensor tendons interdigitate freely over the dorsum of the hand. This prevents retraction, and primary repair is readily accomplished by coaptation and appropriate splinting with the wrist in extension. A single figure-of-eight wire passed through the skin and the tendon approximates the tendon ends (Figure 2-c). Splinting in extension relieves the tension on the suture line; these tendons do not retract far when cut.⁸

Wrist

At the wrist, the extensor tendons are grouped in six compartments under the dorsal carpal ligament, each with a separate tendon sheath. When cut, they retract into the forearm. Primary repair is anatomically more difficult in this area, as it must be accompanied by resection of the mucous sheaths and decompression of the compartments by longitudinal incision of the dorsal carpal ligament.⁵ When all tendons are divided, repair of every one should not be attempted. Primary consideration must be given to providing good extension of the wrist and abduction of the thumb; extension of

Fig. 4 — Applied techniques. *Left*, For primary or secondary suture, figure-of-eight stitch approximates the tendon ends. Splinting prevents tendon ends from being pulled apart. *Right*, Suture-at-a-distance reduces tension on tendon repair. Note excision of sheath overlying repair. (Modified from Boyes, J. H.: *Bunnell's Surgery of the Hand*. Ed. 4, Philadelphia, J. B. Lippincott Company, 1964, 791 pp.)⁸

the fingers and thumb is secondary. The extensor carpi radialis brevis muscle is the most important wrist extensor, and the abductor pollicis longus is the most important tendon on the dorsoradial aspect of the thumb; these should be repaired. Finger and thumb extension can be restored later or given a mass extension action by providing one or two motors to power the extension.⁹

Thumb Extensor Tendons

All lacerations of the thumb extensor mechanism may be repaired primarily and splinted in extension.

When the long extensor tendon is cut over the base of the thumb, it retracts considerably and, because of its angulated position around Lister's tubercle of the radius, repair is more difficult. Primary repair may require that the tendon be rerouted subcutaneously to permit approximation of the ends without tension.

Primary repair of the extensor pollicis brevis tendon, which functions as both extensor and abductor, is desirable but not always essential if the long extensor and abductor tendons are intact. Isolated lacerations of the extensor pollicis brevis tendon cause little deformity and may not be diagnosed. Failure to repair it, however, can result in incomplete extension of the proximal

phalanx and slight imbalance of the hood mechanism.

Repair of the abductor pollicis longus tendon is essential because this musculotendinous unit functions not only as an abductor but also as a stabilizer of the important metacarpomultangular articulation of the thumb. It presents no particular anatomic difficulty in primary repair.⁵

In general, extensor tendon repairs are more satisfactory in the thumb than in the fingers.⁶

Splinting

In all extensor tendon injuries, the wrist should be extended, and the metacarpophalangeal joints should be maintained in slight flexion during the period of immobilization (Figure 4-left). This avoids contractures and imbalance associated with prolonged hyperextension. Splinting is mandatory for at least three weeks, and some protection against the pull of the powerful flexors should be maintained by keeping the wrist splinted for an additional two weeks.³

Flexor Tendon Repair

Whereas extensor tendons are more commonly injured in the nondominant hand, there is a definite tendency for flexor-tendon

Fig. 5 — Flexor tendon repair. (Modified from Holm, C. L., and Embick, R. P.: Anatomical Considerations in the Primary Treatment of Tendon Injuries of the Hand. *J Bone Joint Surg* 41-A:599, 1959;⁵ Kelly, A. P., Jr.: Primary Tendon Repairs: A Study of 789 Consecutive Tendon Severances. *J Bone Joint Surg* 41-A:581, 1959.)⁶

Continued

injury to occur in the dominant hand. In addition, results of tendon repair are much less satisfactory for flexor than for extensor tendons.⁶ In general, therefore, flexor-tendon injuries are more disabling than are extensor injuries.

Wrist

Primary repair of flexor tendons in the wrist is essential and is anatomically practical because the synovial sheaths or bursae terminate in the wrist and blend with the vascular paratenon (Figure 5). Also, the rich blood supply from the musculotendinous junction facilitates primary repair.^{4,5} However, if all 12 tendons and both ulnar and median nerves were sutured at one level, a great, homogeneous mass of scar tissue might result with no functional activity of any tendon or nerve. In such an event the digital superficialis tendons and wrist flexors are of secondary importance and need not be repaired.^{3,4,9} The wrist flexor tendons are in paratenon and will usually repair themselves in a functional manner.⁹ Since speed of repair and utilization of a minimal amount of suture material are often desirable in multiple profundus-tendon anastomoses in one area, the double right-angle suture is frequently used (Figure 2-b).

*Carpal Tunnel**

A laceration extending entirely through the carpal tunnel would sever nine tendons and the median nerve, a situation which makes repair difficult. The median nerve should be repaired initially and, because of excessive retraction of the tendon ends at this level, primary repair of the profundus and flexor pollicis longus should be attempted. The superficialis tendons should be excised as far proximally and distally as possible through the operative wound. They may be sutured only if the suture lines will lie more proximally.⁴ The ulnar bursa, which envelops the profundus from the ulnar side, should be resected or wrapped about the tendon junctures in an attempt to prevent adherence of individual tendon anastomoses to

each other and to surrounding soft tissues. The carpal tunnel should be completely decompressed by incising or excising the transverse carpal ligament. If possible, the junction of the tendon ends should not be placed within the carpal tunnel; this can be avoided by proper positioning of the wrist.^{5,6,8} The double right-angle suture is again used to good advantage.

Palm

Area of Lumbrical Origin on the Profundus.—When the superficialis and the profundus tendons are lacerated in this area, primary repair of both tendons is feasible because the lumbrical muscle can be interposed between them to prevent cross union. The lumbrical muscle should be interposed with minimal suturing to avoid damage to its nerve supply and to avoid limiting its action.³⁻⁵

SHEATH-LUMBRICAL MUSCLE INTERVAL

When only the superficialis tendon is lacerated, it need not be repaired because there will be little loss of function. When both tendons are lacerated in this region, the repair will be influenced by the position of the fingers at the time of injury. Thus, in lacerations through the distal palmar crease with the hand in extension, primary repair of only the profundus is advisable, as no barrier to cross union with the superficialis exists at this level. The superficialis should be excised. If the tendons are lacerated in flexion, the distal ends will move into the fibrous sheath of the fingers when the fingers are extended. In this case it would probably be most prudent to close the skin and perform a secondary graft, because the junction of the tendon ends would lie within the tendon sheaths distal to the metacarpophalangeal joint.⁵

"No-Man's-Land"

This is the critical and complex area of pulleys extending from the insertion of the superficialis tendon on the middle phalanx proximally to the termination of the flexor sheath in the palm.

In the past the standard treatment has been wound decontamination, skin closure,

*See Yamaguchi, D. M. et al.: Carpal Tunnel Syndrome. *Minnesota Med* 48:22, 1965.

and tendon graft at a later date. In the recent literature there are more and more reports of primary repair, but the variety of techniques indicate that there is no conformity or universally good method. Some authors state that injury within the digital sheath can never be repaired with uniformly good results, whether primary repair or late resection and grafting procedures are used.⁴

Important factors in making a decision between primary repair and secondary repair include the surgeon's knowledge, experience, and skill in the management of difficult tendon injuries, the location of transection, the digit involved, the type of injury and associated injuries, the degree of contamination, the age and occupation of the patient, and the available equipment and facilities, including adequate assistance and postoperative management.^{4,6,8,10}

Those who favor wound closure without primary tendon repair^{4,5,8,11-13} believe that, when the superficialis alone is divided, it should be excised. Early motion will maintain profundus excursion and ensure a functioning finger, with no further treatment necessary. When the profundus alone is divided, it should not be sutured, and the superficialis should not be sacrificed but rather strengthened by early motion (Figure 5). Tenodesis of the distal joint could be done primarily or at a later date. Or arthrodesis of the distal joint could be done later; this is indicated particularly for laborers or those who desire a quick, certain result. In an exceptional case, a thin palmaris or plantaris graft could be used secondarily to restore profundus action. Some authors advocate tendon grafts for index and long fingers because they gain pinch. In musicians and skilled technicians, attempts at tendon grafting for all fingers may be warranted. If both superficialis and profundus tendons are divided, neither should be sutured, and tendon grafts should be inserted later (Figure 5). Usually two to three weeks later, the superficialis is excised and a tendon graft replaces the profundus tendon from its distal attachment to

the proximal half of the palm or well into the area of the origin of the lumbrical muscle.

If results are unsatisfactory, tenolysis* may be done but should be delayed at least six weeks to obtain maximal range of motion and to avoid spontaneous rupture of the graft.

Those who favor primary repair^{3,4,10,14-16} of tendons in no-man's-land agree that, when only the superficialis is divided, primary repair is certainly not indicated. Isolated lacerations of the profundus tendon are rare (Figure 5). Primary repair usually results in adhesions to the sublimis tendon. Excision of an intact sublimis tendon in order to facilitate primary repair of the profundus tendon is mentioned only to be condemned. Any primary procedure should be limited to tenodesis of the distal portion of the tendon to the middle phalanx. This then is similar to what is recommended by those who favor wound closure and secondary repair. The real point of contention is what should be done when both tendons are divided (Figure 5). This is a frequent location for tendon injury, and temptation to carry out primary suturing is great.

All who advocate primary suturing insist on "ideal conditions." These include a clean hand at the time of injury, minimal contamination, laceration by a thin, sharp agent, operation within six to eight hours of injury, an incised wound with no crushing or avulsion, adequate facilities and instruments, trained assistants, and experienced surgeons. These advocates point out that any surgeon who is trained to perform a successful graft of the flexor tendons is also capable of performing a successful primary repair. This might well be our guideline. Thus, anyone not capable of tendon grafting should probably not do primary repair. When experience is limited, treatment should be more conservative.

Most who recommend primary repair believe that the superficialis tendon should be excised. The overlying sheath and the pulley structure at the level of the suture must be excised (Figure 4-right). This allows

*See Test Your Word Score Page 63.

good blood supply at the site of repair and ensures that any future scar at the site of suture will slide freely in both directions without contacting the sheath. The remaining sheath suffices to prevent dislocation of the tendon. The profundus should be sutured accurately with fine epitendinous stitches. Tension on this anastomosis may be reduced by the "suture at a distance" technique (Figure 4-right). Verdan¹⁵ advocates fixing each tendon end with a transverse stainless steel pin to prevent tension (Figure 2-d).

Should adhesions hinder gliding, secondary tenolysis often produces functional results better than those of tendon grafts. For multiple simultaneous flexor cuts on several fingers, primary repair may be more justified than for one cut alone. Also, after primary repair, grafting at a later date is still possible but is more difficult than when the wound only has been sutured.

Distal Profundus Area

This area extends from the insertion of the profundus tendon on the distal phalanx to the insertion of the superficialis tendon midway on the shaft of the middle phalanx. Lacerations here involve only the profundus tendon, making primary repair possible. Excessive retraction of the proximal end is prevented by the vincula. Four possibilities exist.^{4-6,10-12}

1. If the laceration is at least 1 cm. proximal to its insertion, both ends of the tendon can probably be found in the wound, and direct approximation with a pullout suture should be easy. The pulley and the sheath in the vicinity of the junction must be excised.

2. If the distal stump is less than 1 cm. long or is frayed or avulsed, the proximal tendon end can be advanced and fixed directly to the distal phalanx. Several techniques are available, including direct suture or burying the tendon end beneath a small osteoperiosteal hole drilled through the phalanx. The junction should be well distal to the interphalangeal joint, thereby avoiding adhesions in the region of the joint and volar plate. Advancement is limited to 1 or

2 cm. if a flexion contracture is to be avoided. Profundus lengthening procedures in the wrist are not practical. If primary suture is not advisable, a secondary repair may be considered if division has been close to the insertion.¹²

3. If the proximal end has retracted into the palm due to muscle pull, the vincula have ruptured; then it is technically difficult to rethread the profundus tendon down its proper channel through the sublimis bifurcation without inflicting further trauma. In most cases it is better to suture the distal tendon end to the middle phalanx with the distal joint in flexion and the fingertip in pinching position.^{4,5,7}

4. If all else fails, arthrodesis of the distal joint in slight flexion leaves little functional disability.^{5,6,8}

Thumb Flexors

The results of flexor repairs are usually more satisfactory in the thumb than in other digits.⁶ The flexor pollicis longus has no vincula and is without a lumbrical muscle; it lies in the carpal tunnel within its own sheath, and its muscle is independent of the finger flexors. Thus the anatomy facilitates tendon advancement or lengthening during primary repair of lacerations.⁵

Distally, the phalangeal portion of the tendon can be repaired primarily, as in the fingers, by the advancement procedure.⁵

In the metacarpophalangeal joint area, direct suture with resection of the sheath is preferred and can be assisted by tendon advancement or tendon lengthening at the wrist if necessary.⁵

In the thenar area, primary tendon repair is possible but, because of hemorrhage and the presence of overlying digital and motor branches of the median nerve, the surgical approach is often difficult. If the nerve is also severed, then both tendon and nerve should be repaired. If the nerve is intact, simple closure of the wound would avoid further damage. Secondary repair by grafting or transfer of the ring finger superficialis tendon is practicable.^{5,10}

In the carpal tunnel and wrist, the thumb flexor tendon is well situated for primary

repair. The sheath must be resected and the tunnel decompressed.⁵

The long thumb flexor acts primarily on the distal phalanx. Therefore, if the long flexor tendon cannot be repaired, arthrodesis of the interphalangeal joint in slight flexion will restore a useful thumb if the thenar motors are intact.

Splinting

In general, when flexor tendons have been sutured, immobilization — with the wrist in flexion, the involved finger in the position of function, and the other fingers extended — is necessary for three weeks; then, active exercises are begun. Exercises against moderate resistance are begun during the fifth postoperative week.

Secondary Repair

Secondary reconstruction of tendons does not always imply tendon grafting. The most conservative operation which gives the best chance of good function with the least risk should be used. Other operative procedures which may be used include delayed suture, tendon advancement, tendon lengthening,

tendon transfer, tenodesis, and arthrodesis. Experimental work on artificial tendons has been in progress for some time and may provide an additional method of treatment for special cases in the future.¹⁷

Summary

A résumé of current concepts in treating lacerations of tendons of the hand has been compiled from the recent literature, supplemented by practical experience. Anatomic considerations have been stressed because these are the basis for treatment. The choice between primary repair and wound closure with secondary repair of a lacerated tendon of the hand is based on experience. Consistently good results from primary repair of flexor tendons in "no-man's-land" are not easily obtained by surgeons who see these injuries infrequently. Physicians not capable of performing secondary repairs — for example, tendon grafting procedures — are probably not qualified to do primary repairs. When experience is limited, treatment should be conservative. One rarely can be criticized for cleansing and closing the wound and seeing that the patient is given adequate follow-up care.

Gleanings from the Meetings

Minnesota State Obstetrical and Gynecological Society Meeting*

Rochester, Minnesota — April 23, 1966

Well, here we are. We have finished the formal presentation. The entire subject of therapeutic abortion is now open for discussion from the floor.

Obviously, Minnesota is not typical of the nation as a whole. We have less than one per cent Negroes, we have far less than the usual number of poor, we have practically no Puerto Ricans, and we have a large rural population. Obviously, all of these things are going to enter into the fact that we have less illegal abortion here than we have in other states. I think the one per cent is somewhat like an iceberg, 99 per cent of which is below the surface.

Question:

Has an obstetrician or other practicing physician been sued for doing a therapeutic abortion in Minnesota after one of these committees has given its permission to go ahead?

Answer:

Only in the State of Pennsylvania has a physician been brought to trial for performing a therapeutic abortion. This man was found not guilty. There has never been one conviction in the United States where a physician has done a therapeutic abortion in a licensed hospital.

Question:

Now surely, gentlemen, this is a critical situation! If you will ask yourself when this occasion arises: Do we have sufficient justification for carrying out the destruction of a child? Do we destroy those babies who have damaged eyes and other defects when they are born? Do we destroy them in the last trimester of pregnancy because they do not have souls? Is there a difference between babies 24 weeks after conception and those after 25 weeks? Have they acquired souls in that one week?

Answer:

I do not have the answers to these difficult questions, and I am certainly no authority on religion. I find myself somewhat in agreement with St. Thomas Aquinas, who thought abortion was allowable before quickening. My point is that these underlying philosophical or theological assumptions are a road block to our finding out what the true situation is. Under the present state of our knowledge and under our present laws we cannot gather the necessary information and the conclusive evidence; this is the thrust of my argument.

*Ed Note: Extracted from the open discussion. Only the sting has been removed.

Continued

Question:

Will liberalization of the law decrease the number of criminal abortions?

Answer:

The very fact that we condone the breaking of a law does not mean we have to change the laws so that we do not break them. I do not mean to imply that liberalizing the abortion law in accordance with the recommendations made by the American Law Institute will decrease the number of criminal abortions. What I am saying is that there are women who are apt to seek criminal abortions if there are not enough physicians willing to do therapeutic abortions. You said that you and the Department of Psychiatry have a perfectly satisfactory arrangement. It may be perfectly satisfactory for the Department of Psychiatry, it may be perfectly satisfactory for the Department of Obstetrics and Gynecology; but I am not so sure that this is perfectly satisfactory for the individual patient.

I hope that you are familiar with the law, because if you are, you realize that any of you who have performed a therapeutic abortion are in a sense felons as the law stands in the Minnesota statutes at present, because it is an extremely rare situation where the life of the mother is preserved even by a medical indication for therapeutic abortion, and to me this is the crux of the problem.

Question:

Are we to permit ourselves to stand in legal jeopardy, or by modification; according to the American Law Institute, will we be able to practice medicine as we understand it in every ethical relationship according to the law of the States?

Answer:

You will find that groups in these same societies are exhorting us to do something about our perinatal mortality. At the present time we are being criticized if we are unable to save more than 97 out of every 100 infants born. I think this problem is so emotionally charged that we find ourselves cheering for one side or the other much as at an Irish soccer match, forgetting the fact that we are primarily physicians and surgeons. We have taken the Hippocratic oath and our responsibility is primarily from the medical aspect of this problem. We, as a part of society, have a great obligation to try to join with the social economic thinkers in making this world a better place in which to live, but I do not feel that as physicians we should assume all the responsibilities for the socioeconomic problems of the world.

We'll excuse our guests, and the business meeting will convene in three minutes.

Abstracts, Briefs and Commentaries

PAGET'S DISEASE OF THE MALE BREAST

James Paget first noted and described cases of areolar eczema followed by female breast cancer in 1874. Darier, 15 years later, established the concept of Paget's disease by the characteristic cells in the epidermis of the nipple. This condition in the male breast is extremely rare. In 1964, Hutchin and Houlihan collected 12 male cases in the world literature and added one of their own, which is reported in detail. Microscopic examination following surgical mastectomy revealed Paget's cells, large, with pale cytoplasm and prominent hyperchromic nuclei, along the malpighian layer of the eroded epidermis. The mass in the breast revealed an infiltrating distal carcinoma. Lymph nodes from the axilla contained metastases.

COMMENT: Paget's disease is said to comprise three to five per cent of all breast cancers, with cancer of the male breast estimated to be one per cent of the frequencies in women. Moss reported one case of Paget's disease out of 50 per cent of male breast cancers. Treves found two cases among 146 and Orase found one among 72 male breast cancers.

Hutchin and Houlihan classified Paget's disease of the male breast in three clinical types: (1) Paget's disease with nipple erosion only; (2) Paget's disease with nipple erosion and a palpable breast tumor; (3) Paget's disease with breast tumor alone. Nipple erosion with palpable breast tumor characterized most cases.

Surgery is the same as for similar carcinomas of the breast in women. The skin incision should be wide and, because of the absence of relaxed tissue as present in the female, skin grafting is usual. The cure rate of cancer in the male breast is comparatively low; Moss reported the five-year survival rate of 248 cases of male breast carcinoma to be 41 per cent. Poor results are due to: (1) hormonal environments quite different in each sex; (2) delayed medical attention in male patients; (3) the smaller size of the male breast, with early tumor infiltration of underlying tissues, skin, and regional lymph nodes.

Paget's disease with erosion of the nipple alone is frequently seen by physicians and dermatologists before a diagnosis is made.

Haagensen suggests that all erosions and dermatitis-like lesions which involve only the nipple epithelium are carcinomatous. Erosions that in-

Continued

volve the areola only or skin of the adjacent breast, leaving the nipple uninvolved, are not Paget's carcinoma.

INSTRUMENT PERFORATION OF THE ESOPHAGUS — WHAT IS CONSERVATIVE MANAGEMENT?

The author describes the treatment of 16 patients who had had 17 instrument perforations of the esophagus during endoscopy. Nine patients had perforations high in the esophagus and ordinarily associated with no organic lesion. All underwent cervical drainage with or without closure of perforation within less than eight hours and received conventional doses of antibiotics. Average hospitalization was eight days. Eight patients had perforation associated with lesions of the thoracic esophagus (achalasia,* carcinoma, benign stricture). Six patients survived and the average hospital stay was 15 days. All had thoracotomies, and four of the surviving six had definitive treatment of their lesion.

The author discussed the "mental attitude" of the endoscopist when perforation had occurred. He felt that definitive surgical therapy was more "conservative" management than nonoperative approach for perforation. This avoided a second thoracotomy if a lesion was present; it also resulted in lower morbidity and mortality.

Comment: A thought-provoking and interesting article that should be carefully considered by all endoscopists.

Jerome Grismer, M.D.
Minneapolis, Minnesota

Groves, Laurence K.: Instrument Perforation of the Esophagus — What Is Conservative Management? J Thorac Cardio Surg 52:1, 1966.

CURRENT APPROACH TO THE SURGICAL MANAGEMENT OF EMPHYSEMA

The current approach to selection for operation is reviewed. Basically, the various tests search for patients with space-occupying, non-functioning lung encroaching upon adjacent more normal lung tissue. The type of surgical procedure preserves the most of normal pulmonary tissue. Nineteen patients had a total of nine bleb excisions, nine lobectomies, and two plications with "denervation." There were no operative deaths but four late deaths, three from respiratory failure within 24 months. Tracheotomy was used in nine patients.

Although there was immediate subjective improvement in 11, only five maintained this. Pulmonary function tests did not improve postoperatively.

The authors are seeking to correlate objective factors (angiography, lung scan, work of breathing, etc.) with subjective factors. In select patients the operations appear rewarding.

Comment: A difficult disease to treat by any method, emphysema offers a challenge to each and every physician. Because of its chronicity in the patient, the physician becomes dulled to aggressive management, continued reevaluation, and objective tests as to the result of therapy.

Jerome T. Grismer, M.D.
Minneapolis, Minnesota

Benfield, J. R., Cree, E. M., Pellett, J. R., Barbee, R., Mendenhall, J. T. Hickey, R. C.: Current Approach to the Surgical Management of Emphysema. Arch Surg 93:59, 1966.

BORIC ACID POISONING

An infant boy seemed in good health until, when he was three weeks old, his mother noted purplish mottling of his face. Next day he did not take the bottle well, was "breathing very hard" and vomited. He became less responsive and his respirations were irregular. He was dead when taken to St. Christopher's Hospital.

After the autopsy the child's mother related that she had dusted his diaper area freely with pure boric acid powder at every change of diapers for several days before his death. She had been told by her mother that boric acid was the best remedy for the infant's diaper rash.

Autopsy revealed much vacuolization of the acinar cells of the pancreas. Many of these vacuoles contained definite inclusions, some acidophilic and other faintly basophilic. Unfortunately the tissues were lost before toxicologic surveys could be performed but the mother produced an almost empty cardboard container of U.S.P. boric acid which she had been using, and there was no doubt of boric acid poisoning.

In two other fatal cases of boric acid poisoning in infants toxicologic examinations were performed. In both cases inclusion bodies were demonstrated in the acinar cells of the pancreas.

Intercytoplasmic inclusions in the pancreas due to boric acid poisoning were first reported by Fisher in four autopsies in 1951. He concluded that this finding alone was diagnostic of the disease. Greater awareness of the occurrence and significance of this apparently specific morphologic change would be valuable to pathologists in general and particularly to those dealing with infants and children.

Of 172 published cases of boric acid poisoning 83 were fatal; 78 were in adults and 94 in children. Boric acid poisoning still occurs frequently: at the Poison Control Center of New York City from 1955 to 1960 185 accidental cases were recorded. Of the 158 cases of household poisoning with boric acid reviewed by Gold in 1949, 30 were due to the application of pure boric acid to the denuded diaper area, and 23 were fatal.

Lister first used boric acid as an antiseptic in 1875, and it is still used extensively by the medical profession and others. Apparently many professional and nonprofessional people are not aware that this drug can be lethal. For every conceivable medical use of boric acid there now seems to be a more effective and safer agent.

In concentrations over 2 percent boric acid inhibits phagocytosis, and at 4 percent its toxicity to the tissues is greater than its bactericidal activity. When it is dispensed by drugstores to lay customers the containers should be clearly labeled "poison."

Moliere on Doctors — II*

Seventeenth century French audiences were delighted with Moliere's Physician In Spite Of Himself (Le Medecin Malgre Lui), wherein the author satirized the medical profession of his time. In this gay and uninhibited comedy Sganarelle, a mere woodcutter, is prevailed upon to don the conventional physician's gown and peaked cap and impersonate a doctor to prescribe for a lovesick girl who is feigning muteness — with inability to utter more than a series of anks, eeks, and onks. In diagnosing the case Sganarelle pontificates:

"I maintain that this obstruction to the tongue's action is caused by certain humours, which we scientists call peccant** humors. Peccant, that is to say . . . peccant humors. Since the vapors caused by the exhalation of the influences which arise in the diseased area, arriving. . . you might say . . . at . . . Now these vapors I refer to, making a passage from the left side, where the liver is, to the right side, where the heart is, it comes about that the lungs, which we call in Latin *armyan*, having a communication with the brain, which we term in Greek *nas-mus*, by means of a vena cava, which we denominate in Hebrew *cubile*, encounter on their path the aforesaid vapors — because the aforesaid vapors have a certain malignity, which is caused by the acridity of the humors engendered in the concavity of the diaphragm, it then happens that the vapors — ossabundus, nequeys, nequer, potarinum, quipsa milus. And that is exactly how it comes about that your daughter is dumb."†

Vastly impressed, yet slightly puzzled by this unmitigated gobbledegook, Geronte, the girl's father, ventures:

"There is just one thing that bothers me: the position of the liver and the heart. It seems to me that you place them wrongly; and the heart is on the left side, and the liver on the right."†

This slight incongruity Sganarelle cavalierly dismisses by announcing:

"Yes, that is the way it used to be. But we have changed all that; now we use an entirely new method in medicine."†

Whereupon the subdued Geronte murmurs:

"Oh, I didn't know that. I ask your pardon for my ignorance."†

After a felicitous outcome for which the imposter Sganarelle deserves none but takes all the credit, he concludes:

"If things go on this way, maybe I'll stick to medicine for the rest of my life. I think it's the best trade there is, for whether you do well or badly, you get paid just the same. We never get blamed for doing a bad job; and we cut the cloth we work on to please ourselves. A cobbler making shoes can't spoil a piece of leather without paying for the damage; but in this job we can spoil a man without its costing us a penny. The blunders aren't our fault; they're always the fault of the man who dies. In short, the nice thing about this profession is that dead men have a marvelous decency and discretion; you never hear a dead man complain of the doctor who killed him."†

Whereunto an associate replies:

"It is true that the dead are uncommonly polite on this subject."†

Book Reviews

Books were only invented to aid the memory. — Petrarch

SYNOPSIS OF NEUROLOGY — Second Edition, Francis M. Forster, C. V. Mosby, Publication Date 7-15-66, Price \$7.50.

This small nicely bound synopsis is written by a single author and is quite readable. Its purpose is to instruct the reader in the manner of evaluating a patient from a neurological standpoint and to point up the highlights of the major neurological disease entities. It should prove to be valuable to students wishing to review the field but will be of little help to the clinician for refinements in diagnosis; and treatment of specific disease entities are necessarily deleted.

EPIDEMIOLOGICAL STUDY OF CANCER AND OTHER CHRONIC DISEASES — National Cancer Institute, Monograph 19, January 1966, U. S. Department of Health, Education and Welfare, Public Health Service, National Cancer Institute, Bethesda, Maryland, 465 pages.

This monograph is dedicated to the career of Harold Dorn, distinguished statistician, who died in May 1963. Dorn initiated the massive study of smoking done in recent years on government life insurance policy holders which continued from 1954 to the present. From this study a few impressive statistics can be quoted. An eight-and-a-half-year follow-up of just under 300,000 U. S. Government life insurance policy holders showed the following increased mortality risks associated with cigarette smoking, compared with those who have never smoked: 1.7 for deaths from all causes, 10.9 for lung cancer, 12.2 for emphysema, and 1.6 for coronary heart disease. Paralysis agitans is the only cause of death associated with significantly lower mortality for smokers than for nonsmokers. The risk for cigarette smokers was much greater than that for pipe or cigar smokers. Current smokers of cigarettes, pipes, or cigars experienced a mortality risk significantly greater than for nonsmokers, if they smoke more than four pipes or four cigars daily, or more than an occasional cigarette.

The very high degree of association found between cigarette smoking and death rates from pulmonary emphysema is paralleled by histologic findings of a close association between cigarette smoking and changes in the lung parenchyma,

including rupture of alveolar septa, fibrosis and an increase in thickness of walls of small arteries and arterioles. The association found between cigarette smoking and death rates from coronary heart disease is paralleled by histologic findings of a high association between cigarette smoking and the degree of atherosclerosis in the coronary arteries. The major portion of this monograph concerns studies on cigarette smoking and cancer.

This monograph is a reference work providing the statistical evidence of the pathological effects associated with smoking. It is not recommended for reading by the general public or by the general medical public. However, that portion of the medical profession which still persists in smoking, if they consider themselves still amenable to a logical argument, might benefit from perusal of the Dorn study of smoking and mortality among U. S. Veterans reported in this work. There is no logical ground left for the physician who denies the ill effects of smoking. The arguments for smoking are reduced therefore to illogical arguments. It is difficult to attack an illogical position with a barrage of logic. The smoker retreats into the realm of fantasy to protect his habit. This reviewer has been singularly unsuccessful in his attempts to control the smoking habits of his patients.

INTERNATIONAL SYMPOSIUM ON GENES AND CHROMOSOMES — Edited by: Professor Juan I. Valencia and Dr. Rhoda F. Grell. For sale by: The Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Price: \$3.50

This book is National Cancer Institute Monograph No. 18, published December, 1965, by the U. S. Department of Health, Education, and Welfare, Public Health Service, National Cancer Institute, Bethesda, Maryland, and is the proceedings of the International Symposium held at Buenos Aires, Argentina, November 30 to December 4, 1964. This book would be of limited value to a practitioner of medicine in the diagnosis or treatment of his patients. However, this symposium on research and teaching in bacterial genetics and human cytogenetics would be a valuable addition to the library both for study and for reference for any researcher in these fields.

9500 miles from Danang, Americans are fighting another enemy.

Inflation is a threat to every family's paycheck . . . to the strength of our nation itself. And while other Americans are engaged in the fight for freedom half way around the world, we must be increasingly alert to the dangers of inflation here at home.

American businessmen can help maintain a stable economy and curtail inflationary pressures through the Payroll Savings Plan for United States Savings Bonds. Money invested in Savings Bonds is actually an investment in the United States. It results in more effective

management of the public debt, maintains the value of the dollar and provides a firm base for family security.

In your plant or office, you can initiate and promote this program for systematic savings. Complete information is available from your State Savings Bonds Director or by writing the Treasury Department, United States Savings Bonds Division, Washington, D.C. 20226.

in your plant . . . promote the PAYROLL SAVINGS PLAN for U.S. Savings Bonds

The U.S. Government does not pay for this advertisement. It is presented as a public service in cooperation with the Treasury Department and The Advertising Council.

Special Article

The Abortion Problem

J. L. McKELVEY, M.D.*
Minneapolis, Minnesota

THERE ARE serious stirrings by small but vocal groups of mixed physicians, pastors and laymen who advocate the liberalization of the indications for abortion in the human. Such groups have organized themselves both in Los Angeles and in New York City. A similar start has been made in Minnesota. It is difficult to be certain just what these proponents wish. Some statements suggest a desire for liberal laws which accept present practice. But may this not really be an initial move toward a gross extension of the legal indications for induction of abortion. Most of the proponents are frank about this.

Groups of physicians have been questioned as to their attitudes. It is difficult to know how representative these groups are or how much they have read or thought about the problem. They are quoted as being largely in favor of extending the indications for fetal destruction.

Those who have serious doubts as to the wisdom of such change and as to the reliability of the data on which it is proposed have either hesitated to argue publicly or given the impression that they speak from rigid prejudice. It would seem that this whole matter is important enough to justify an attempt to examine it with as much objectivity as any of us can muster. The hope is that this will lead to some careful thinking.

There are two chief arguments for changing the present legal status of therapeutic abortion. *The first is* that, in general, the law is so out of date that the responsible physician is forced into occasional illegal acts in order to adequately care for his pa-

tients. The threat of punitive legal action has stopped some physicians from doing what they consider right and has led some hospitals to forbid such procedures. *The second argument* is that this attitude has forced patients, particularly those who are poor, into the hands of criminal abortionists with the attendant risks of permanent damage or destruction. It is assumed that if abortions could be obtained at the wish of the patient, they would be done in hospitals and these risks would disappear.

The proponents generally support a 1959 recommendation of the American Law Institute. Their model for legislative action by the states was as follows: "A licensed physician is justified in terminating a pregnancy if he believes there is substantial risk that continuance of the pregnancy would gravely impair the physical or mental health of the mother, or that the child would be born with grave physical or mental defects, or that the pregnancy resulted from rape or incest."

One may be justified in some concern when this is followed by: "But for millions of other women with valid reasons for desiring an abortion, there can be no safe, painless, legal solution to their plight." "The medical profession is intimidated and confused. In the name of observing the law, shameful injustice is committed."** "They fail to recognize—the serious danger to persons or families faced with unwanted pregnancies."† The indications would thus be extended to "desiring an abortion" and an "unwanted pregnancy."

It is clear that the acceptance of all of this involves of necessity an agreement with the conclusion that the child or fetus or whatever one wishes to call it is not a devel-

oping human or that it is without any claim to the right of protection and so may be destroyed without compunction at the convenience of an adult. Is this acceptable by the thoughtful physician?

The Law

There are said to be no Federal laws dealing with abortion induction. The states have handled the problem in a variety of ways.

Preservation of Life and Health

The details of these do not need to concern us here. In general, they allow the interruption of a previable pregnancy for the purpose of "the preservation of life and/or health of the mother." An occasional strange one adds the life and health of the fetus. The value of an abortion for this purpose is not clear. In some states the only indication is the preservation of the life of the mother. There is, I believe, no state which has legalized as an indication a possibly damaged fetus. The dreadful thalidomide experience and the more recent confusing publicity about intrauterine rubella infection has brought this back to the fore. It is clear then that doctors have been acting in disregard of the law in two directions. They have been doing abortions which had no legal justification. And they have been dishonestly ascribing the indication for abortion to the preservation of the mother's life or health when they knew very well that this was untrue.

Rubella

Some reputable physicians in San Francisco have aborted women who had rubella in the first trimester. They purposefully brought this to the attention of the local law enforcement authorities who were thus forced to act. Most of us are seriously disturbed about this. It would seem that a lay jury inflamed by emotional lawyers is scarcely the ideal quiet reasoning group to decide such an issue.

There are a considerable number of problems which stand in the way of an ideal solution. Let us ask ourselves a few questions.

Purpose of the Law

What is the purpose of an abortion law? It is clearly the expression of a sort of public

consensus that it is wrong to destroy a developing human. The developing human fetus or baby or whatever one wants to call it can produce serious embarrassment to adults under a variety of circumstances. There is, then, the temptation to destroy it. The accumulated wisdom of a sort of common law concludes that this is wrong and has set up penalties for unjustifiably yielding to the temptation.

Preservation of Host

Gradually, certain qualifying situations have developed. The physiologic and, in some cases, pathologic changes in the host which are the result of pregnancy can on occasion produce destructive effects on specific organ systems so that the host's life is endangered. Under these circumstances the fetus and placenta are aggressors. The practical feature is of course that if the mother dies the previable or aborted fetus will also die. Does one allow both to die or is there justification for removing the pregnancy in the hope of preserving the mother's life? Medical opinion would seem to agree on this. The catch lies, of course, in the skill, the judgment and the honesty of the physician who determines the risk. How great should the risk be to justify interference? These are things which can be neither adequately described in a law nor reasonably decided in a court room. How much risk of progression of a maternal disease process justifies destruction of a child? How accurate is the assessment of this degree of risk?

Moral Law

The public has realized this and has placed an astonishing degree of faith in the careful honesty of the physician. They have tolerated his breaking of the law on occasion with the assurance that he will act with good medical judgment and complete honesty. No physician need fear the law under these circumstances. It is not right to say that the medical profession is intimidated and confused. I am not. But it should be perfectly clear to all physicians who are involved in these things that the very fact that such laws are broadly written and that the public trusts the physician to do his

own interpreting, puts on the medical group the responsibility to think clearly, to act with complete intellectual honesty and to discipline itself to stay within the limits of generally accepted morality. The physician must not run off on his own radical path when it involves the public trust and the taking of a life. All of us know and can document the fact that this is not universally accepted, which is a pity.

The public has gradually softened its attitude toward the mother who aborts herself or obtains what is known as a criminal abortion. There was a time when the law under the influence of the Christian Church actually required the crucifixion of such women. This sympathy seems to have spilled over on the criminal abortionist, who is likely to be given only a minor penalty unless the mother has been killed as well. Now there appears to be an organized push to greatly extend the indications for abortion.

British Common Law

This involves some strange thinking. The world was horrified when Hitler destroyed children en masse. All of us would bitterly condemn one who wilfully destroyed a recently delivered viable baby. This includes, of course, the premature delivered after 28 weeks of pregnancy. British common law separated infanticide as a crime and abortion as a misdemeanor at the time the fetal movements are felt, which is usually about eighteen weeks after the last menses. It would seem that a widely held opinion has developed which holds that suddenly at about this four to five-month point something happens which changes a piece of living tissue like an appendix into a human with rights of protection. What is this change and when does it occur? People who pretend to some specially dispensed information not available to the general public have given what they consider to be learned dissertations on the soul and its entry into the developing human. What is this soul? Where is it? When does it enter a developing fetus? At one time it was concluded by the learned that the soul entered the body of the male and the female at different durations of pregnancy. What evi-

dence is there to support all this? What evidence is there that a baby at three months of development is different in this respect from one at four or five or six or ten lunar months? You can amuse yourself with the silly arguments in the literature dealing with these points. The Yen-an Chinese will not bury a young child in the same burial place as the adult because, in their considered opinion, the child's soul had not yet entered him. Does the intelligent person dare to use this sort of reasoning to decide when his responsibility to another human begins? And, if he cannot do this as an individual, how can the group apply this to the extension of a rational law? It should be clear then that destruction of an intra-uterine fetus at any point in its career is infanticide and can be justified only under the most exceptional circumstances. In the University of Minnesota clinical material, this appears to occur once in about four or five years. The indications do not include "millions of other women with valid reasons for desiring an abortion," or "the persons or families faced with unwanted pregnancies." There are solutions for these difficulties short of taking a human life, and personal experience has borne out the effectiveness and reality of this conclusion.

American Law Institute

In the light of all of this, let us look at the details of the model code recommended by the American Law Institute. What is meant by the adjective substantial? Can this be interpreted so that a commonly accepted definition could be achieved? This would allow — as you very well know — the finding of an excuse to abort every woman who requested it. Every unmarried mother, every patient with anemia, with three other children, with a drunken husband, or who can claim to be depressed will be prime candidates. These indications are not reasons for fetal destruction, but they have been and will be used as excuses to get rid of a pregnancy which the patient doesn't want at the moment. If this involved only hospitalization, some anesthesia and a minor surgical procedure, one would shrug his shoulders and

Continued

not worry too much. Unfortunately, it involves taking a life and that is another matter.

Very strange things are presently going on which involve the interpretation of indications for abortion. The interested reader is referred to a study by Dr. Robert Hall (*Am. J. Obs-Gyn.* Vol. 91:No. 4: p. 518, February 15, 1965) which details the experiences of Columbia University Medical School at Sloane Hospital in New York City. The experiences of a great many other hospitals throughout the country are listed. One hospital in New York City listed 4501 ward deliveries (1960-1962) and five abortions (1:900) as against 2023 private patient deliveries with 101 abortions (1:20). How do you interpret this? What are the realities of the indications which are being applied? What is meant by "substantial risk?" Do we really wish to legalize abortion for each twenty term pregnancies? To kill one baby in twenty?

Indications

The indications for destruction of pregnancies seem to change rapidly. In one hospital, the ratio of abortions to live births was 1:141 for ward and 1:37 for private patients. A therapeutic abortion board was established whose permission was required for the procedure. Following this the ratio was 1:429 for ward and 1:111 for private patients. The obvious questions do not need to be listed. What would be the effect of the application of a rule of "substantial risk?"

Some time ago, the indications were largely based on organic disease. Gradually these were demonstrated to be for the most part either unreal or problems which could be handled by other means than abortion. It is fairly easy to document the proof of this so that disagreement is hard to justify. An astonishing shift has now occurred, largely in the private patient group. The indications are now psychiatric in about two thirds of the patients. These are much harder to document. Most of us have come to the conclusion that there is no psychiatric indication whatever for abortion. The psychiatric problems can be handled effectively in other ways. The suicide rate in women is less than

in men by 4 or 5 to 1. Depressions can be recognized and treated. There has been no suicide in an unmarried mother in Minnesota since 1957. There is no psychiatric disease which can be cured by abortion. There are some very obvious questions to ask about the sudden shift of indications and the strange difference between the indications in private and in ward patients. Again it isn't necessary to list these.

Intrauterine Damage

The problems associated with the possibility of intrauterine damage from chemicals or infections have suddenly come to the fore. The infection about which most is known in detail is that of syphilis. Oddly enough, this did not raise the question of mechanically destroying the fetus of an infected mother. Attention was focused on rapid recognition and treatment of the disease, which eventually proved to be remarkably effective. Let us remember that forty or fifty years ago, syphilis in the pregnant mother was infinitely more frequently encountered than rubella in recent times and that the fetal infection rate and the resultant disasters were at least as severe. It was, then, a much greater problem than rubella. Should we have destroyed somewhere between 5 and 15% of the fetuses because of the risk of fetal syphilis?

This leads on to the worrisome features of the model code inclusion of "substantial risk—that the child would be born with grave physical or mental defects." What is the order of "substantial risk" here? Since rubella infection is the major application of this at present, let us look at a sample of what we know of this risk. This is done with the clear understanding that there seems to be good evidence that the risk to the fetus varies in different epidemics.

Rubella In First Trimester
(Combined Reports of Lundstrom, Manson and Pitt)
Risk of Severe, Disabling Lesions In Surviving Child

Cataracts and blindness	2%
Severe deafness	6%
Disabling heart lesions	1%
Mental deficiency	1-1 1/2%
(Mental deficiency in general population)	1%
Real risk of one or more lesions	7-10%

This is the sort of information one must use in deciding what the order of a given risk may be. But this begs the question of the basis on which one will use it. Do I have the right to kill a considerable number of developing humans who are normal in order to get rid of the painful problems of the occasional child who is born alive with an abnormality which may be minor or severe? Understand that no one is cured of anything in the process. Do I indeed have the right to kill a human, developing or developed, because it has an abnormality? Is the three or four-month fetus a developing human? Each of us must answer these questions carefully and honestly for himself. It is perhaps absurd to suggest a compromise. If one believes that he is justified in destroying a child because it has an abnormality would it not be better to give legal blessing to waiting until the babies are born at term, letting those who are normal survive and handling the abnormal ones with a hammer since they are now too big for a curet? This is a horrible thought, but isn't it really more sensible and humane than indiscriminate destruction of the normals and abnormals, the so-called King Pharaoh technique? If I were a normal fetus at risk I should certainly think so. It is recognized that perfectly honest students of the problem will disagree. For myself, I cannot avoid the conclusion that my duty is to preserve life insofar as possible and that I have specifically sworn not to purposefully destroy human life. Like the syphilis problem, it would rather seem that we should try to control the disease. There is every reason to believe that this can be done. If one can convince the physician of the justification of these conclusions, the presence or absence of specific legal permission would seem to be of little importance. There is no desire to either punish the person who honestly disagrees or open the legal abortion door wide to the careless or dishonest person. The object is to encourage critical, responsible thought. The courtroom is not the place to achieve this.

What about the horrible problem of the baby who has been exposed to thalidomide

or methotrexate? Here the abnormalities are very much more frequent and more severe. One can only settle these problems for himself. The prime necessity is, of course, prevention. The reputable physician who depends on his own honest conclusions in this and a number of other infrequently occurring problems has no need of specific legal permission.

Rape or Incest

And what of pregnancies which result from rape or incest? It is difficult to define rape. There is good reason to believe that a vaguely large proportion of rape involves at least some cooperation and indeed is often an afterthought. If one puts a reward on such afterthought, as the legal removal of an unwanted pregnancy, the result may not be unexpected. The abortion door will be opened wide and the general public invited in. If the rape or the incest is real, destroying the fetus will not change the fact that it has occurred. It will only partially hide the evidence from the general public at the expense of destruction of the most innocent individual of the three. Again, is the three or four-month fetus a developing human? Can we take human life for the convenience of an adult? The simple fact is, of course, that there are other methods of sympathetic handling of the mother which are at least as effective as abortion. In spite of the fact that a British jury has disagreed, there seems to be no reason other than sympathy for specifically legalizing abortion for rape or incest. All of us will be sympathetic toward the girl and bitter toward the male who caused the disaster. We would do anything in the world to help her short of destroying an innocent individual.

What now are the advantages of changing the law? Under present circumstances, a reputable physician can carry out his decisions without fear of reprisal providing only that they satisfy the public consensus of what is reasonably justifiable. His colleagues or the hospital authorities will act as reasonable brakes but will support him in an honest informed decision.

Changing the law would appear, then, to

Continued

have another significance. It is reasonable to assume that such change is designed to allow extension of the indications. For the reasons stated above, one must object to that.

Criminal Abortions

The Danger

There can be no question but that a great many women seek out dangerous methods of one sort or another to remove unwanted pregnancies. The degree of danger is likely to be related to the ability of the patient to pay the abortionist. Under ideal circumstances, abortions can be done with very little vital risk. The procedures which are open to the poor on the contrary can be very risky not only to the life of the individual but to her future health. If these abortions were indicated on the basis of the public consensus of what is justified, they could and many would be done in a qualified hospital, by a trained and reputable physician and so safely. The only conclusion is that they do not satisfy these requirements and so, since they involve destruction of a fetus, justify the term criminal abortion. No one knows how many of these are done or how many women are damaged or destroyed by them. Estimates which have been as high as 5 to 10,000 deaths from this cause each year in the United States would represent more than 150 as Minnesota's share. The detailed Minnesota Maternal Mortality Study is extremely unlikely to miss any of these. In actual fact, Dr. Alex Barno* has shown that there were 20 such deaths in Minnesota in 15 years to 1964 or $1\frac{1}{3}$ as a yearly average. Higher risk calculations are based on California and New York. It would seem clear that if one wanted to stop abortion deaths, the best solution would be to remove women of childbearing age from these states. The incidence per unit of population elsewhere may be greater than in Minnesota but not that much greater. The suggestion is that the estimate is excessive.

Suffering and Damage

The suffering and damage, both physical and emotional, is unquestionably great and

one would like to do anything he could to remove even a part of it. It has been suggested that if the indications for legal abortion were extended to include the simple wish to get rid of an unwanted or embarrassing pregnancy, this suffering could be avoided, and "millions of other women with valid reasons for desiring an abortion —" (Lader) would be happily and safely treated in reputable hospitals. There is evidence from areas where abortions are carried out at the patient's wish that this hope has not been realized. What is perhaps more potent in considering this proposition is the same old issue. Are these developing humans and can we justify slaughtering them by the millions? Can one justify Pharoah's approach? What these people need is help, human comfort, and an arm around the shoulder rather than fetal destruction. I have been through this sort of thing so often that I feel justified in the conclusion that I am right and that the problems can be handled by other means. Indeed, they can be handled much better by other means.

William Ober, a pathologist in New York, lists the details of two patients in a series of very radical recommendations in the October 8, 1966 *Saturday Evening Post*. One is a 34-year-old married woman who had some sort of pelvic infection associated with an intrauterine fetal death at five months some seven years prior to the present problem. She is now pregnant again, which means that her pelvic infection is either cured or was originally questionable. "She became deeply fearful of having another pregnancy — and is terrified. For two weeks she has cried; she cannot stand the sight of her children." Dr. Ober wants her aborted. It does not require a special skill for the clinician to recognize a seriously emotionally-ill, depressed patient. She needs competent psychiatric care in a hurry. She will not be cured by an abortion and may even be made worse by this procedure.

Unwanted Pregnancy

The other patient is a fourteen-year-old pregnant by a friend of her father. He is described as "a perfectly reputable business man," which one finds hard to believe.

*See page 11.

Does one kill an innocent fetus because of this man's disgusting activities? Will this procedure wipe out the rape? Dr. Ober says, "I believe that every woman should be able to have an unwanted pregnancy aborted at her own request subject only to the consent of her husband and the advice of her physician." It is this sort of attitude which seriously worries the vast majority of thoughtful laymen and, I believe, of physicians. It is this sort of admission which justifies one's suspicion that it is not really a change in the law to conform to present day knowledge, but a vast extension of indications for abortion which these groups really intend. The alternative to this is the extension of social services, of related education, of available contraception and, where indicated, of sterilization. Above all, doctors and nurses must be ready to offer kindness, understanding and patience to the distraught woman. She needs a friend and help rather than an abortion or a changed law. The problem really is to find her and to get her into such hands.

Indications for Abortion

It is not possible to go extensively into this field. A good deal of the problem has already been mentioned. Prevention of the difficulties is, of course, an ideal solution and the application of this is obvious. There are some medical or surgical indications for therapeutic abortion which are still accepted, but the vast majority of these have vanished in the light of experience and factual data. In general, the removal of a pregnancy is justified only when it can be demonstrated to be a really dangerous aggressor.

Some very strange things have been turned up in studies of indications which have been applied. The astonishing dissimilarity of the incidence of indications in those who can and those who cannot pay for the procedure has already been mentioned. It could be held that the private patient rate is justified and that the underprivileged group are having adequate medical care in hospitals withheld from them in spite of the fact that, in many instances, both groups are being cared for by the same staffs. Logically this should move the abortion incidence in

the opposite direction for a number of reasons.

In another study, 40% of those aborted were unmarried, widowed or divorced. The indication here would seem to be readily identified as the convenience of an adult.

In still another study, done in Sweden in 1958, 100 women who had been aborted in the interests of "the health of the mother" were followed. Within three years, 70% of them were pregnant again and delivered without a single serious complication. In still another, 50 were given permission for an abortion but decided against it. There were no deaths in the group and "nine reported improvement in their mental health." The confusions here are obvious. The original indications were largely non-existent.

Psychiatric

The most confounding aspect of the problem is the psychiatric one. There can be no doubt of the reality of the sudden switch from the indication of organic disease to that of emotional disturbance. In one study, psychiatric indications changed from 15% in 1940 to 80% of the hospital abortions at present. One is constantly astonished at the apparently universal ease with which psychiatric consultation can be obtained to agree to abortion. The author knows of it being accomplished over the telephone without even seeing the patient. Apparently a large segment of the psychiatric group hold to the concept that "if a woman does not like being pregnant, she has a right to have it removed." No psychiatrist will ever tell me at what point in the duration of the pregnancy this changes, although all agree that it is best to destroy the child before it is born alive at term. Are these people right and are those of us who would deal more conservatively with our responsibilities to human life wrong and old-fashioned?

Let us be clear, however, about the reality of the arguments regarding a psychiatric indication. There is no psychiatric disorder which can be cured by an abortion. The author, in spite of repeated efforts, has never been able to get a psychiatrist con-

Continued

sultant to write as part of the indication that the abortion will cure the psychiatric disorder. Indeed, the pregnancy may on occasion be used as a lever to pressure the patient into adequate psychiatric care. As in some organic diseases, so here. The patient may well be better off pregnant and adequately treated than not pregnant and without treatment.

Risk of Suicide

In the socially troubled and depressed patient, the risk of suicide has been given as an indication. Lindberg has followed 27 women who were pregnant and threatened suicide. No single one carried out the threat. Barno has studied the Minnesota material. There were 14 suicides in pregnant woman in the 15-year study and among 75 to 80,000 live births a year or among a total of 1,232,500 live births. This is about 1 per 100,000 live births per year as compared to 3.1 to 5.2 per 100,000 females of all ages. There was no single suicide in an unmarried mother. There were two schizophrenics and 12 psychotic depressions. At least these 12 should and, in most instances, could have been recognized and appropriately handled. Ten of the 14 committed suicide post partum, so that a physician had an excellent chance to recognize the risk. He had had them under his care during the stress of pregnancy and delivery. Indeed four of the 14 were under psychiatric care. In none of the 14 had there been a request for abortion. It would appear then that the pregnant woman in Minnesota carries $\frac{1}{3}$ to $\frac{1}{5}$ the suicide risk of the general female population and that those who do commit suicide can largely be prevented from doing so. This can then scarcely be considered as a real indication.

Passage of Heredity

One is more concerned about the hereditary or environmental passage of the emotional disturbance to the child. The second of these is probably much the more important of the two and its handling is obvious.

Sterilization of the chronically psychiatrically disturbed patient may be clearly indicated.

At the University of Minnesota, then, abortions are not done for psychiatric indications. The recognition and treatment of the emotional disorder is carried out instead; and, for what it may be worth, experience has shown this to be a satisfactory decision. The patient is sick, and the pregnancy is normal. Abortion for this reason then would not seem to be indicated. Should we encourage the reverse attitude by legalizing abortion for "the substantial risk of impairing the mental health of the mother" and, if so, who is to determine this and on what reliable data?

There are more data from studies dealing with the effect of the abortion on the emotional well-being of the patient. There is not time to consider this in detail. The author has been horrified to see the ravages of the guilt sense in a considerable number of women and their consorts who had undertaken criminal abortions. The end results of removing an unwanted pregnancy are certainly not as simple and uninvolved as one might think at first glance.

Conclusions

From all of this, there arises the hope that physicians and nurses and particularly our own group in this mid-Northwest will conclude that our voluntarily accepted duty is to try to progressively increase the efficiency with which we can save lives and obviate human suffering. And, unless we can establish without question the fact of a vital fetal aggression which cannot be handled in any other way, that we shall avoid the purposeful taking of a human life for whatever other reason and no matter what the law allows. For my own part, I shall struggle against a legal breach in the dike, however small, in the fear that a flood will follow. There is reason to believe that a flood is planned.

Success is a journey and not a destination. — Advertising Age

In Memoriam

We understand death for the first time when He puts his hand upon one whom we love. — DeStael

WALLACE E. ANDERSON, M.D.

Dr. Wallace E. Anderson, 58, Clearbrook physician, died November 12. Born at Wing, North Dakota, Dr. Anderson received his degree in medicine at the University of Minnesota. He was formerly associated with Dr. O. F. Melby at Thief River Falls; however, following his discharge from the armed services in 1946, he moved to Clearbrook where he has been practicing for the past twenty years.

Dr. Anderson was a past-president of the Red River Valley Medical Society, a member of the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife and a son.

EARL BRUCE TRUCKER, M.D.

Dr. Earl Bruce Trucker, 34, pathologist at the Hennepin County General Hospital, died November 28. Born in Minneapolis, Dr. Trucker graduated from the Harvard Medical School in 1958.

He was a member of the Hennepin County Medical Society, Minnesota State Medical Association, and the American Medical Association.

He is survived by his wife, three sons, and a daughter.

HENRY B. CLARK, JR., M.D.

Dr. Henry B. Clark, Jr., professor and head of the department of oral surgery in the University of Minnesota's School of Dentistry, died December 3, after a long illness. He was born in Oak Park, Illinois, and graduated from the University of Minnesota with a doctor of medicine degree in 1933. He interned and then entered the School of Dentistry in 1936.

Dr. Clark served on the board of directors of the

Minnesota Cancer Society, was president and counselor of the Minnesota section of the International Association for Dental Research; served on the international professional relations committee of the Ramsey County Medical Society; was president of the Minnesota Society of Oral Surgeons, a member of the Ramsey County Medical Society, Minnesota State Medical Association and American Medical Association.

He is survived by his son and three daughters.

ROGER W. MARKS, M.D.

Dr. Roger W. Marks, 54, former Dakota County coroner, died December 25, in St. Luke's Hospital, St. Paul. He had served as coroner eight years and resigned last September because of illness. Born in St. Paul, he graduated from the University of Minnesota Medical School.

He was a member of the Ramsey County Medical Society and American Medical Association and an associate member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

HENRY JOSEPH REIF, M.D.

Dr. Henry J. Reif, 58, St. Cloud physician, died December 21. He was born in St. Paul and lived there for thirty years before moving to St. Cloud in 1946 where he had a general practice. He was a graduate of the University of Minnesota Medical School.

He was a member of the Stearns-Benton County Medical Society, Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, two daughters and two sons. Dr. Robert W. Reif of White Bear Lake is his brother.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Births	1955 through 1964	Total: 9,500
Therapeutic abortions	1955 through 1964	Total: 0
Committee Rules	Information not given.	

Medical Poll of Desired Indications for Therapeutic Abortion

Questionnaire

In this analysis, the answers were recorded as "Yes" or "No" when a definite opinion was given. There was a third group tabulated as "Unanswered." In this third group the question was left blank; the person stated he would have to have more information to answer the question, or the answer was so qualified that it meant nothing definitely either for or against the procedure.

Of the two hundred (200) votes returned, one hundred six (106) were from psychiatrists and ninety-four (94) from obstetricians.

There were eight (8) of the 106 psychiatrists or 7.5% that voted straight "Yes" and two (2) of the 94 obstetricians or 2.1% that voted a straight "Yes" for liberalizing all of the indications given for therapeutic abortion.

Ten (10) of the 106 psychiatrists or 9.4% voted a straight "No" and fourteen (14) of the 94 obstetricians or 14.8% voted a straight "No" ballot. They would not do any therapeutic abortions. One of this group, however, stated that he would suggest that the patient see another doctor in any of the given circumstances, if the patient so desired.

There were eighty-eight (88) of the 106 psychiatrists or 83.0% and seventy-eight (78) of the 94 obstetricians or 82.9% that were in favor of liberalization of some of the indications for doing therapeutic abortions.

Questionnaire

These figures and percentages are divided into — (1) Obstetricians and (2) Psychiatrists.

Do You Believe A Pregnancy Should Be Interrupted:

- | | | |
|---|-------------|-------------------|
| I. When the life of the mother is in danger? | | |
| 1) Yes 77-81.9% | No 15-15.9% | Unanswered 2-2.1% |
| 2) Yes 93-87.7% | No 12-11.3% | Unanswered 1-0.9% |
| II. When the physical health of the mother might be impaired? | | |
| 1) Yes 54-57.4% | No 35-37.1% | Unanswered 5-5.3% |
| 2) Yes 72-67.9% | No 27-25.4% | Unanswered 7-6.6% |
| III. When there is significant risk that the mental or emotional health of the mother might be jeopardized? | | |
| 1) Yes 44-46.8% | No 45-47.8% | Unanswered 5-5.3% |
| 2) Yes 75-70.7% | No 28-26.4% | Unanswered 3-2.8% |
| IV. When there is significant risk that the child would be born mentally or physically defective? | | |
| 1) Yes 51-54.2% | No 38-40.4% | Unanswered 5-5.3% |
| 2) Yes 79-74.5% | No 25-23.5% | Unanswered 2-1.8% |
| V. When the pregnancy resulted from rape or incest of a girl under 16? | | |
| 1) Yes 63-67.0% | No 28-29.7% | Unanswered 3-3.1% |
| 2) Yes 84-79.2% | No 19-17.9% | Unanswered 3-2.8% |
| VI. When the pregnancy resulted from rape or incest of a girl over 16? | | |
| 1) Yes 50-53.1% | No 41-53.6% | Unanswered 3-3.1% |
| 2) Yes 70-66.0% | No 30-28.3% | Unanswered 6-5.6% |
| VII. Whenever the woman requests it? | | |
| 1) Yes 1- 1.1% | No 90-95.7% | Unanswered 3-3.1% |
| 2) Yes 8- 7.5% | No 95-89.6% | Unanswered 3-2.8% |

13 Obstetricians	75 Obstetricians	6 Obstetricians
14 Psychiatrists	72 Psychiatrists	20 Psychiatrists

The Minnesota Obstetrical and Gynecological Society

The Minnesota Obstetrical-Gynecological Society, at their recent meeting, held December 3, 1966, in Minneapolis, Minnesota, decided to inform the Council of the Minnesota State Medical Association and the appropriate Legislative Committee the results of a post card poll of its members on "Therapeutic Abortion."

The post card poll gave the members three choices:

1. Favor the present Minnesota Statute on "Therapeutic Abortion."*
2. Favor the Model Penal Code of 1959.*
3. Favor some changes, but not Penal Code of 1959.

Out of 157 cards sent, 104 cards were returned, 23 favoring the present statute; 66 favoring the Penal Code of 1959; 15 favoring the third choice.

The Society preferred to take no official action as representing the Society.

*See page 48.

St. Luke's Hospital Seminar

St. Luke's Hospital, St. Paul, is presenting a seminar entitled "Clinical Aspects of Hematology" on April 27, 1967, starting at 1:30 p.m. in the St. Luke's Hospital auditorium. The featured speaker will be Dr. A. J. Quick of Marquette University Medical School. Contact: C. E. Turbak, M.D. at St. Luke's Hospital.

Meetings and Announcements

The discipline which corrects the baseness of worldly passions, fortifies the heart with virtuous principles, enlightens the mind with useful knowledge, and furnishes it with enjoyment from within itself, is of more consequence to real felicity, than all the provisions we can make of the goods of fortune. — Blair

Norinyl[®] tablets

(norethindrone 2 mg. $\bar{c}$ mestranol 0.1 mg.)

for multiple contraceptive action that has produced a record of unexcelled effectiveness

**inhibition of ovulation by means of
2 time-proved hormonal agents**

**production of a cervical mucus hostile to
sperm motility and vitality**

**creation of an endometrium unreceptive
to egg implantation**

no unplanned pregnancies

Norinyl provides multiple action for maximum assurance of success. It does not depend on ovulation inhibition alone for contraceptive effectiveness. The mechanism of action of combined hormonal therapy results in ovulation inhibition reinforced by other protective mechanisms, including a hostile cervical mucus¹⁻¹³ and an acceleration of endometrial changes.^{1-3,7-16} With Norinyl, no unplanned pregnancies have been reported to date when used as directed.

plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.

Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to con-

firm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-

ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism. **Side Effects:** Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

Norinyl tablets
(norethindrone 2 mg $\bar{c}$ mestranol 0.1 mg)

for multiple contraceptive action

Now, now, Mrs. Forsythe, we've never lost a cold patient yet.

When she's experiencing acute discomfort from cold symptoms, it's small wonder the patient becomes distressed about her condition.

She will breathe easier when you prescribe Novahistine LP.

Novahistine LP is a long-acting decongestant that helps restore normal mucus secretion and ciliary activity—physiologic mechanisms which prevent infection of the respiratory tract. A dose of two tablets taken in the morning and repeated in the evening will usually keep air passages clear for 24 hours.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution patients who operate machinery or motor vehicles that drowsiness may result.

Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

Your Bank Accounts

IN OUR BUSINESS, it is fairly common for us to find clients with large accumulations of money in checking, savings, and saving or building and loan accounts. Quite frequently, there are sound investment reasons for our recommending substantial transfer to other mediums.

This recommendation is especially valid for checking accounts which provide no yield whatsoever. Every \$1,000 of excess checking balance costs its owner at least \$40 annually in sacrificed earnings. In the case of savings accounts, we must determine whether an imbalance exists between fixed dollars and variable commitments, before recommending transfers of large sums.

Recent embezzlements, by bank employees in the Midwest, of very substantial sums have highlighted another reason for limiting the funds in a bank account. This reason is simply excess risk exposure.

By far the most outstanding example of this risk exposure is the recent embezzlement of over \$2 million by a trusted employee and stockholder in a Sheldon, Iowa bank. This defalcation has directly or indirectly contributed to the complete insolvency of the bank, bankruptcy of one of the leading industries in that town and the threat of crippling losses to numerous persons with over \$15,000 on deposit with that bank.

If you carry more than \$15,000 in a bank account,

you also may be unduly exposed to such a loss, and it's too late after you read about the embezzlement in your local paper. If investment logic alone does not dictate limitations on your bank accounts, certainly safety factors do.

The Federal Deposit Insurance Corporation and the Federal Savings and Loan Insurance Corporation provide full protection on bank and savings and loan accounts up to \$15,000. This \$15,000 is *per entity*, that is the individual, joint, partnership or corporate account.

In the case of a husband and wife, it would be possible for them to be fully insured on \$45,000 of deposits in one bank — if the accounts are properly designated. The husband can have \$15,000 in his name, the wife \$15,000 in hers, and an additional \$15,000 will be insured in a joint account. *Two* accounts in the *same name* are insured only once — for \$15,000.

Beyond this \$45,000 level, husband and wife should place their funds in a second bank or savings and loan organization. Above all, money should never be deposited with an institution not participating in the Federal insurance program.

If you are carrying excess funds in your checking or savings account, you have a two-fold interest in reducing them. Both investment principles and safety reasons dictate a revision of these accounts.

Minnesota State Board of Medical Examiners

The Minnesota State Board of Medical Examiners and the State Examining Committee for Physical Therapists have announced that persons desiring to take the examination for registration of physical therapists must be graduates of a school of physical therapy approved by the Board for training physical therapists, in addition to the other statutory qualifications. Persons interested in determining their eligibility to take the examination for registration in physical therapy are advised to contact the Board in order to insure that the school they propose to attend is one approved by the Board.

Minnesota Obstetrical-Gynecological Society

The next meeting of the Minnesota Obstetrical-Gynecological Society will be held in Duluth, April 29th. The following doctors will be the guest speakers:

Howard Jones, M.D. — subject to be announced

Georgianna Jones, M.D. — Role of Estrogens in the Aging Female

The Doctors Jones are husband and wife and are from the Johns Hopkins Hospital in Baltimore.

Contact: Theodore Watson, M.D., 1261 Lowry Medical Arts Building, St. Paul.

Physician's Diary

When a great merchant of Liverpool was asked by what means he had contrived to realize the large fortune he possessed, his reply was, "By one article alone, in which thou mayest deal too, if you pleasest — it is civility." — Bentley

NEW LOCATIONS: Dr. Arlo Pitcher is the new physician in St. James . . . Dr. William D. Brown, Jr. has opened up new offices in Minneapolis . . . Doctors Mustafa Vidinli and Wilfred Pinsonneault have joined the Delmore Clinic in Roseau . . . Dr. J. E. Nord has begun a practice at the Hawley Medical Center in Hawley . . . Dr. Andrew Steiner has left St. Michael to open up a practice in Minneapolis. Dr. Nick Koropchak has joined the staff of the Fridley Medical Center in Fridley.

* * *

Dr. Jesse E. Edwards, Charles T. Miller Hospital, St. Paul, is the newly elected president of the American Heart Association.

* * *

Dr. C. G. Uhley has retired from the staff of the Northwestern Clinic in Crookston after almost thirty years of association. He and Mrs. Uhley intend to spend their retirement in Palm Desert, California.

* * *

Dr. O. J. Swenson of Waseca was honored by that community on occasion of his 40th year in the practice of medicine in Waseca. An open house reception was held.

* * *

Dr. D. B. Soriano, recently on the staff of the Willmar State Hospital, has joined Doctors G. T. Midboe, J. L. Purdie, C. F. Peikert at the Doctors Clinic in Forest Lake.

* * *

Dr. Tague Chisholm is the new president of the Hennepin County Medical Society, and Dr. James C. Mankey is the secretary.

* * *

Dr. Malcolm Campbell, Rochester, was elected president of the Zumbro Valley Medical Society. Other newly elected officers were: Dr. David Utz, vice president, and Dr. Martin Van Herik, secretary-treasurer, both of the Mayo Clinic.

* * *

Dr. O. K. Behr was elected chief-of-staff and president of the Medical Staff at Bethesda Hospital in Crookston at its annual meeting in November. Dr. J. S. Rubin was elected vice president, and Dr. Robert Schnable, secretary.

* * *

Dr. Robert A. Ulstrom, chairman of the pediatrics

department of the Center for Health Sciences at the University of California, has been named associate dean of the College of Medical Sciences at the University of Minnesota. He assumed his new post December 1st.

* * *

Dr. Samuel M. Reichel, Minneapolis, presented a paper at the annual meeting of the American Association for Automotive Medicine at Holloman Air Force Base, Alamogordo, New Mexico in November. The title of the paper was "Moderate Auto Injuries: The Role of Reflexes in Pathogenesis and Symptomatology."

* * *

Dr. George B. Logan, a member of the Section of Pediatrics of the Mayo Clinic, was chosen president-elect of the American Academy of Pediatrics at the annual meeting of the organization in October.

* * *

Dr. Laurentius O. Underdahl, head of a section of medicine at the Mayo Clinic, was inducted as president of the Minnesota Society of Internal Medicine at its annual meeting in October, and Dr. John A. Spittell, Jr., head of a section of medicine in the Mayo Clinic, was elected secretary-treasurer.

* * *

Dr. Karl W. Anderson, retired vice-president and medical director of Northwestern National Life Insurance Company in Minneapolis, has been elected president of the Minnesota Medical Foundation. Dr. N. L. Gault, Jr., associate dean of the University of Minnesota College of Medical Sciences, was re-elected secretary-treasurer.

* * *

Dr. Howard Polley, Mayo Clinic specialist in rheumatic diseases, was elected vice president of the Arthritis Foundation at its annual meeting in November, and Dr. Arthur Bulbulian, emeritus member of the Mayo Clinic staff, has been re-elected editor of the American Academy of Maxillofacial Prosthetics.

* * *

Dr. Wendell Hall, professor, Department of Internal Medicine, University of Minnesota School of Medicine, and on the staff of the Veterans Administration Hospital, received an unrestricted grant for medical research from Wyeth Laboratories.

3 a.m.

**Sleep-interfering
anxiety and tension
can usually be relieved
with
EQUANIL[®]
(meprobamate) Wyeth**

Cautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. After prolonged high dosage, drug should be withdrawn gradually to avoid possibly severe withdrawal reactions including epileptiform seizures. Side effects include drowsiness and, rarely, allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Warn patients of possible reduced alcohol tolerance. Should drowsiness, ataxia, or visual disturbances occur, dose should be reduced. If symptoms persist, patients should not operate vehicles or dangerous machinery. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Other blood dyscrasias—aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia—have occurred rarely, almost always in the presence of known toxic agents. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. Prescribe very cautiously for patients with suicidal tendencies. Suicidal attempts should be treated with immediate gastric lavage and appropriate supportive therapy.

Contraindications: History of sensitivity to meprobamate.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Wyeth Laboratories
Philadelphia, Pa.

fluocinolone acetonide — an original steroid from

SYNTEX 

LABORATORIES INC., PALO ALTO, CALIF.

controls infected inflammatory dermatoses that start from scratch

Neo-Synalar®
fluocinolone acetonide-neomycin sulfate cream)
Cream

The "itch-scratch" cycle usually associated with inflammation often results in infected dermatoses because broken skin surfaces are particularly vulnerable to pathogenic bacteria.¹ To treat infected inflammatory dermatoses, Neo-Synalar Cream combines the most active topical corticosteroid with a highly reliable antibiotic generally reserved for topical application.

In Neo-Synalar, fluocinolone acetonide controls the inflammation and provides rapid relief from associated pruritus. At the same time, its antibacterial component—neomycin—combats superficial infection caused by many gram-positive and gram-negative bacilli² that often colonize and thrive on abraded skin.¹

A specially formulated vanishing cream base that is greaseless and odor free makes Neo-Synalar cosmetically appealing, and encourages greater patient cooperation.

controls the infection

stops the scratch

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of its components. **Precautions:** Neomycin rarely produces allergic reactions. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. **Side Effects:** Side effects are not ordinarily encountered with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Neo-Synalar under certain conditions. **Availability:** Neo-Synalar Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

References: 1. Pillsbury, D. M., Shelley, W. B., and Kligman, A. M.: A manual of cutaneous medicine, Philadelphia, Saunders, 1961, p. 79. 2. Barber, M., and Garrod, L. P.: Antibiotic and chemotherapy, Baltimore, Williams and Wilkins, 1963, p. 111.

**How long will it take him
to recover from the flu
if he just doesn't care?**

**Does he really care?
Is he alert, encouraged,
positive and optimistic
about getting out of bed
and back to work soon?**

**Or is he giving in to
the depressing impact
of confinement?**

**When functional fatigue
complicates convalescence,
Alertonic can help...**

Pleasant-tasting Alertonic is pipradrol hydrochloride—an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that so often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

Adequate dosage is important: Prescribe Alertonic—one tablespoonful t.i.d., 30 minutes before meals...tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Alertonic®

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B₁) (10 MDR*), 10 mg.; riboflavin (vitamin B₂) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B₆), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.

†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

Sinus headache is not a single entity,
but a chain reaction of pain.
It is facial pain—deep, dull, aching and
nonpulsating. It is referred pain—
originating in the nose and sinuses but
felt at another site. It may become
generalized pain and tension in head and
neck. It is one or all of these.

The Sinutab formula is designed
for symptomatic relief of sinus headache.

It provides two analgesics to relieve
pain and discomfort...an effective oral
decongestant to reduce mucosal congestion...
and an antihistamine to help
control allergic manifestations.

Side Effects: Epigastric distress, drowsi-
ness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive
or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid
disease, heart disease, hypertension, diabetes
or kidney disease. Excessive dosage or
prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

FOR RENT: Space available for surgical subspecialists. Excellent location. Near Unity Hospital, 10 minutes from Mercy. Share space with General & Thoracic Surgeon and 2 interns. Call Mrs. Winkel — 560-1700, Fridley.

WANTED: General surgeon, qualified or certified. Six man group in Minnesota. Fully accredited 150 bed hospital, open staff. Further information. Write: Falls-Starekow Clinic, Thief River Falls, Minnesota.

IMMEDIATE OPENINGS for full-time or part time **PHYSICIANS** to staff the University Health Service. Good opportunity for semi-retired M.D. Limited call duty. Professional qualifications with first correspondence. Contact Director: K. L. Nelson, M.D., Texas A&M University Hospital, College Station, Texas 77841. Telephone (AC 713-846-4704).

FOR LEASE IN TWIN CITIES — small clinic, large parking area. With lease goes incredibly lucrative general practice, patients' records and excellent staff, at **NO FEE**. Write: **MINNESOTA MEDICINE — 371; 496 Lowry Medical Arts Building, St. Paul 55102.**

INTERNIST AND GENERAL PRACTITIONER wanted to join a four-man clinic group in suburban Minneapolis. Laboratory and X-ray with part-time radiologist. Excellent open hospital staff association. Salary to start with early partnership. Write: **MINNESOTA MEDICINE — 372; 496 Lowry Medical Arts Bldg., St. Paul 55102.**

RESIDENCIES IN PHYSICAL MEDICINE and Rehabilitation offer challenge and opportunity in a growing field. Comprehensive training utilizing Mayo Clinic facilities and faculty, at \$3600 to \$10,000 stipend. Attractive community, excellent school system, cultural advantages. Contact Gordon Martin, M.D., Mayo Graduate School of Medicine, Rochester, 55901.

REALLY LIVE — ON THE ST. CROIX. Your own retreat. Nearer skiing — dock your boat. Spring Company has several. Contact: Harold Onstad, Marine on St. Croix. Call 663-8261.

WANTED: Locum tenens for large general practice St. Paul, Minnesota for February 1967. Salary open. Write: **MINNESOTA MEDICINE — 369, 496 Lowry Medical Arts Building, St. Paul 55102.**

GENERAL PRACTITIONER needed to take over my very active practice on or before June 1, 1967. All equipment nearly new. Records extremely complete. Contact: Gerald E. Cotton, M.D., Fosston, Minnesota.

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of **MINNESOTA MEDICINE** the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in **MINNESOTA MEDICINE**. We can use many more pictures than we have received in the past.

Surgical Meeting

A dinner meeting of the Minneapolis Surgical Society will be held February 2 at the Minneapolis Club in Minneapolis at 6:00. The following speakers will be guests of the Society for that evening:

Donald A. Bolt, M.D. — Trauma in Genesis of Pancreatic Cyst and Pseudo Cyst

David E. Raab, M.D. — Surgical Treatment of Atrial Septal Defect

Let's get
down to earth
about
diuretics

With Hygroton, you'll discover that you can almost always use fewer tablets than is possible with other diuretics.

You may be told that a new short-acting diuretic was found more effective than Hygroton in congestive heart failure — but this was when twice the manufacturer's maximum recommended dose was given.* At the maximum recommended dose for both diuretics, two tablets of Hygroton were far and away more effective than five tablets of the other diuretic in producing natruresis and weight loss. And at these dosages, Hygroton costs only $\frac{1}{3}$ as much as the other diuretic.

Since the discovery of chlorothiazide, the trend has been away from short-acting, multiple-dose, high-cost diuretics. With Hygroton you can usually do the job with just one tablet a day, or every other day.

More than any of the newer diuretics, Hygroton brings dosage and cost of medication down to earth.

*Brest, A. N., et al.: J. New Drugs 5:329, 1965.

Hygroton®
chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water. **Contraindications:** Hypersensitivity and most cases of severe renal or hepatic disease. **Warning:** With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind. **Precautions:** Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. **Side Effects:** Dizziness, weakness, nausea, vomiting, hyperglycemia, hyperuricemia, headache, muscle cramps, postural hypotension, constipation, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin reactions, including urticaria and purpura, epigastric pain, or G.I. symptoms after prolonged administration. **Average Dosage:** One tablet (100 mg.) with breakfast daily or every other day. **Availability:** Tablets of 100 mg. in bottles of 100 and 1000. For full details, see the complete prescribing information. 6524-V(B)

Wait, Annabelle. Mommy hasn't told
the doctor yet that you *need* a shot.

Maybe she does, maybe she
doesn't. But if her problem is
nasal congestion due to cold
or allergy, consider the medi-
cation that combines conve-
nience and effectiveness—
Novahistine Melet.

Melet is especially suitable
for the treatment of children. It's
pleasant tasting, chewable
and leaves no aftertaste
or gritty, undissolved particles

in the mouth. It provides decon-
gestant action almost as quickly
as a liquid, but assures the
accurate dosage of a tablet.

Because Melets are so con-
venient to carry and so easy to
take at any time, adults, too,
will appreciate this modern
dosage form.

Use cautiously in individuals
with severe hypertension, dia-
betes mellitus, hyperthyroidism

or urinary retention. Caution
adults who operate machinery
or motor vehicles that drowsi-
ness may occur. Each Melet
contains phenylephrine hydro-
chloride 10 mg. and chlor-
pheniramine maleate 2 mg.

NOVAHISTINE[®]
MELET

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis

*when agitation
accompanies
spasm of the
'G. I.' tract.*

ButadonnaTM

BUTABARBITAL SODIUM, 15 MG. (BARBITURIC ACID DERIVATIVE)
WARNING: MAY BE HABIT FORMING
BELLADONNA EXTRACT (TOTAL ALKALOIDS 0.188 MG.), 15 MG.

*provides gentle,
intermediate sedation and
relaxes 'G. I.' spasm.*

Butadonna quiets the "brain-on-gut" influences by providing the smooth, intermediate sedative, butabarbital sodium, desirable in combination with the proven antispasmodic, belladonna extract. Butabarbital sodium is more rapidly eliminated than phenobarbital, and avoids the latter's cumulative effect.

Indications: Antispasmodic-sedative. Useful in the treatment of peptic ulcer, gastritis, duodenitis, irritable colon syndrome, ulcerative colitis, regional enteritis, and other conditions associated with gastrointestinal spasm. Also may be useful in functional dysmenorrhea.

Usual adult dosage is one tablet 3 or 4 times daily as needed.

Caution: Contraindicated in glaucoma and urinary retention. Reduce dosage or discontinue use in event of blurring of vision, dryness of mouth, tachycardia, or excessive drowsiness. Continued use of butabarbital sodium may be habit forming.

Minnesota Medicine at a Glance

Corn Allergy — Johnson

Page 35

Of fifty consecutive patients who had food allergies, twenty-five were allergic to corn. According to Dr. K. J. Johnson, corn should be considered one of the most important causes of food allergy. Females seem to have allergies to corn more than males, and most drugs in tablet or capsule form are apt to contain corn.

Cerebral Blood Flow — Meyer and Handa

Page 39

Cerebral blood flow, electroencephalogram, and oxygen consumption were measured in regionally anesthetized, immobilized, and artificially ventilated monkeys. The cerebral venous flow remained unchanged until a temperature of 39-39.4° C. was reached. Thereafter, cerebral venous flow increased to a maximum of 30-50% above steady state values at 41.5-41.9° C. Cerebral metabolic rate for oxygen was also increased significantly (35% on the average) between 40-42° C. When the rectal temperature exceeded 42° C., both cerebral venous outflow and cerebral oxygen metabolism decreased rapidly and the electroencephalogram became abnormal. If hyperthermia was sustained at 41° C., there was a progressive decrease in cerebral venous flow and cerebral oxygen metabolism, and the EEG became progressively abnormal.

Under the conditions used in these experiments, cerebral blood flow and oxygen metabolism remained constant during hyperthermia up to 39° C. Above this level both were increased, and above 42° C. cerebral oxidative metabolism, blood flow, and electroencephalogram failed. Increases in cerebral blood flow and metabolism appear to be relatively smaller than increases of systemic circulation and metabolism reported by others during hyperthermia.

Lacerations of Hand Tendons — Peterson and Lipscomb

Page 101

Lacerations of the tendons of the hands may be complicated and disabling injuries. Successful repair depends on accurate evaluation of the injury, knowledge of the intricate anatomy of the hand, training in the technique of tendon repair, judgment and experience. The authors review the pertinent surgical anatomy of the hand; emphasize the need for proper operating-room conditions for evaluation and treatment; and review the current methods available for successful tendon repair. When conditions are not optimal, and when uncertainty exists as to what to do, it is usually never wrong to perform a toilet and debridement of the wound and close the skin. This will ensure uncomplicated primary healing and enable a successful secondary reconstruction.

The Center of Self-Esteem

Use the knife and the cautery to cure the intumescence and moral necrosis which you will feel in the posterior parietal region, in Gall and Spurzheim's centre of self-esteem, where you will find a sore spot after you have made the mistake in diagnosis. — Osler

It is by the goodness of God that in our country we have those three unspeakably precious things: freedom of speech, freedom of conscience, and the prudence never to practise either of them. — Mark Twain

When the stagnant sinus must be drained...

Transillumination of the sinuses — diffuse shadow on right side of face indicates unilateral maxillary sinusitis.

In the common cold, Neo-Synephrine is unsurpassed for reducing nasal turgesence. It stops the stuffy feeling at once. It opens sinus ostia to re-establish drainage and lessen the chance of sinusitis. With Neo-Synephrine, in the concentrations most commonly used, decongestion lasts long enough for extended breathing comfort, without endangering delicate respiratory tissue. Systemic side effects are virtually unknown. There is little rebound tendency.

Neo-Synephrine[®] HCl

Brand of phenylephrine hydrochloride

is available in a variety of forms,
for all ages:

- 1/8% solution for infants
- 1/4% solution for children and adults
- 1/4% pediatric nasal spray for children
- 1/2% solution for adults
- 1/2% nasal spray for adults
- 1/2% jelly for children and adults
- 1% solution for adults (resistant cases)

Also NTZ[®] Solution or Spray
Antihistamine-decongestant

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Mike expects a penicillin injection. He's about to be pleasantly surprised.

His physician is going to prescribe an oral penicillin — **PEN•VEE® K** (potassium phenoxymethyl penicillin). It's usually so rapidly and completely absorbed that therapeutic serum levels are produced in 15 to 30 minutes. Higher serum levels generally last longer than with oral penicillin G.

Indications: Infections due to pathogens susceptible to oral penicillin G. Prophylaxis of rheumatic fever in patients with previous history of the disease.

Precautions: Skin rash, symptoms resembling those of serum sickness, or other manifestations of penicillin-allergy may occur. Measures for treating anaphylaxis should be readily available: epinephrine, oxygen and pressor drugs for relief of immediate allergic reactions; anti-

histamines and corticosteroids for delayed effects. Penicillin may delay or prevent the appearance of primary syphilitic lesions. Patients with gonorrhea who are suspected of concurrent syphilitic infections should be tested serologically for at least 3 months. Where lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. As with other antibiotics overgrowth of nonsusceptible organisms may occur; if so, discontinue and take appropriate measures. Treat β -hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent development of rheumatic fever or glomerulonephritis.

Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity

Composition: Tablets—125 mg. (200,000 units) and 250 mg., (400,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

Wyeth Laboratories Philadelphia, Pa.

ORAL **PEN•VEE® K**
(potassium phenoxymethyl penicillin)

President's Letter

THIS LETTER will serve both as a warning and as a plea. Some of you who read this message will know all about the story, but the great majority will not have heard it. Please tolerate and read the rather prosaic background information which must be given to you first, in order to get to the punch lines coming later.

Beginning in the winter and spring of 1961-62 a program was started which was entitled the "Minnesota G.P. Psychiatric Training Program." Since that time a total of about 165 physicians have completed the prescribed curriculum. The courses have been splendid "refreshers" in psychiatry given in such a way that all who took them could understand the material, and every effort was made to bring the entire course "close to home" for all participants.

Until July, 1966, these seminar courses were carried out under the aegis of Dr. David J. Vail, Medical Director to the Department of Public Welfare. He has now turned its operation over to the Minnesota State Medical Association, under the direction of Dr. Richard Magraw of the University of Minnesota Medical School.

The idea is beginning to catch on faster now, but not fast enough, because it is not adequately funded. Having had the privilege of being in private practice for many years and knowing what a high percentage of my patients had either frank psychiatric illnesses or psychosomatic disorders, I was able to appreciate the value of these seminar courses such as we had, and which are now being held in various sections of the State.

Over the years, and especially after attending these seminars, I learned to take care of many of the more seriously ill psychiatric patients, both before as well as after they had been under the care and guidance of private psychiatrists or had been returned to their communities from the several State Mental Hospitals.

Now that I have been in the St. Peter State Hospital working with these people for the past two years, I have been able to see more clearly than I did before the real urgency for you as physicians to become familiar once again with these problems. It is equally important for you to be willing to take care of these folks when they are returned to your care from private or public psychiatric hospitals. As far as I am concerned, it makes no difference whether you are a family physician or a specialist, all of you need to know better how to deal with these people when you see them. They comprise the bulk of your practice in one way or another, and too many of you tend to slough them off as "neurotics" instead of learning how to handle them as effectively as you can.

These folks come to you because they want you in preference to someone else, and you can do them a tremendous service by trying to care for them, difficult though many of them are. If you don't do it, and if they keep wandering from one doctor to another, they will eventually wind up being cared for by some "quack" or agency.

Carcinoma of the Pancreas and the Ampulla of Vater*

Treatment of

YOSHIO SAKO, M.D., Ph.D.**
Minneapolis, Minnesota

RADICAL PANCREATICODUODENECTOMY for carcinoma of the ampulla of Vater was introduced to surgeons of this era in 1935 by Whipple, Parsons, and Mullins.¹ Subsequently the two-stage operation was converted into a one-stage procedure, and in later years a number of minor changes were made, especially in the steps in reconstruction. In 1937 Brunschwig reported on the first radical pancreaticoduodenectomy for carcinoma of the pancreas.² There followed a wave of optimism for the operative procedure, but this was relatively short-lived among surgeons at large. As various clinics reported their experiences and the results were evaluated in the light of the operative mortality, the extent of prolongation of life and the relatively small number of five-year survivals, opinions have been voiced periodically that perhaps radical pancreaticoduodenectomy should be abandoned in favor of a less extensive palliative operative procedure. Recurrences have been reported as late as nine years after operation.³ Multicentric origin, of course, cannot be ruled out in such patients.

Despite the understandable lack of enthusiasm for the operation, abandonment of the procedure is not in keeping with progress. The operative mortality for pancreaticoduodenectomy is steadily falling and approaching 10% in a number of clinics. Abandoning of radical pancreaticoduodenectomy may deprive chances for cure to those who present with a picture of carcinoma of the head of the pancreas but who, in actuality, have an ampullary carcinoma which is well known to be potentially more curable than carcinoma of the head of the pancreas.

Incidence

Carcinoma of the pancreas accounts for 1

*Presented at the Minnesota Surgical Society Meeting, November 5, 1965.

From the Department of Surgery, University of Minnesota and Veterans Hospital, Minneapolis, Minnesota.

*See Test Your Word Score Page 221.

**Associate Chief, Surgical Service, Veterans Administrative Hospital.

to 2% of all carcinomas and is second in frequency to pancreatitis as a disease of the pancreas. Pancreatic carcinoma may occur in children and in young adults, but the majority of patients are in their fifth through seventh decade of life. Carcinoma of the pancreas occurs five times more frequently than ampullary carcinoma, and two thirds of the lesions occur in the head of the pancreas. The ductal type comprises 90 to 95% of the carcinomas and is the most malignant form. The tumor may also arise from the acini and the islet tissue.

Clinical Course and Pathology

The carcinoma may be only one half to one third of the actual tumor mass, usually the central portion, with pancreatitis accounting for the remaining areas. The tumor spreads relatively early to contiguous areas because of its retroperitoneal position and because the capsule is thin and there is no peritoneal coverage over much of the pancreas. The lymphatic drainage is rich and perineural spread occurs early. Its close relationship to and early involvement of many vital structures such as the portal vein, superior mesenteric artery and vena cava limit the resectability rate.

The usual clinical history of patients with carcinoma of the pancreas in its early stages contains very little to suggest the correct diagnosis. Physical, laboratory and x-ray findings cannot be depended upon at the beginning. The onset is insidious, and in many patients the symptoms are of a general nature common to a number of disorders such as biliary tract disease, peptic ulcer, and pancreatitis. By the time the so-called classical signs appear, 80 to 90% of the patients have passed the stage where complete surgical excision is possible; they will die of their disease in a few months.

Abdominal pain, jaundice, anorexia, and weight loss of insidious onset but becoming persistent are the major manifestations of carcinoma of the pancreas. Tumor compression of the pancreatic duct may produce pancreatic deficiency and result in changes in character of the stools. With involvement of the common duct there will be onset of

jaundice, and usually this is the single event which makes the patient seek medical aid.

Silent Growth

Carcinoma of the body and tail of the pancreas tends to grow silently for a longer period than in the head of the pancreas and then to cause severe pain as a predominant symptom. Jaundice occurs late and is usually a sign of wide extension of the tumor. The pain of carcinoma of the body of the pancreas is rather typical. Paroxysms of pain may begin near the umbilicus and radiate to the back. They may occur three to four hours after eating or may be totally unrelated to food intake. Relief is sought by the patient by sitting up and leaning forward or lying on the side with the legs drawn up. When these patients seek medical aid, the relative absence of positive physical findings and the occurrence of complaints out of proportion to the physical findings create a diagnostic problem. The generally distraught nature of these patients may on occasion be interpreted as a psychiatric disorder.

Progressive Jaundice

In carcinoma of the ampulla of Vater jaundice may be the first sign that all is not well. Initially the degree of jaundice may vary, but inevitably it becomes persistent and increasingly severe. Edema at the ampulla or slough of a portion of the tumor may cause intermittent obstruction. Jaundice tends to precede pain in ampullary carcinoma, but taken as a group, pain is the predominant early symptom of carcinoma of the pancreas and of the periampullary region.

When jaundice is present, hepatic function tests are useful in the differential diagnosis of obstructive jaundice. The serum bilirubin and alkaline phosphatase levels are high in extrahepatic biliary obstruction. Fecal urobilinogen output of less than 10 mgm. is diagnostic of high-grade biliary obstruction.

The relationship between diabetes and carcinoma of the pancreas is not clearly established, but when a patient in his sixties presents sudden onset of diabetes and particularly if the diabetes is difficult to manage

and there is weight loss and abdominal pain, carcinoma of the pancreas should be suspected. At times an abnormal glucose tolerance test may be an early clue.

Phlebitis

Migratory phlebitis has long been associated diagnostically with carcinoma of the pancreas. There appears to be no greater incidence of phlebitis in carcinoma of the head of the pancreas, but carcinoma of the body and tail of the pancreas is definitely associated with more than the expected incidence of phlebitis.⁴ An elevated blood trypsin level appears to be related to the accelerated blood coagulation. Thrombogenic substances have been observed in the blood of patients with other types of carcinoma such as carcinoma of the stomach, lung, and certain of the ovarian tumors; hence the increased incidence of phlebitis is not peculiar to carcinoma of the pancreas.

The findings on physical examination in patients with early carcinoma of the pancreas may be very scant. An abdominal mass is rarely palpable because of the relatively deep position of the pancreas. Usually, the gallbladder is readily palpable because of the distensible extrahepatic biliary system, in contrast to the gallbladders of patients with calculus obstruction (Courvoisier's law).

Laboratory Observations

The occurrence of blood in the stools is suggestive of duodenal erosion or ampullary carcinoma. Signs of pancreatic insufficiency are in general a late sign. Duodenal aspiration and examination for alteration in pancreatic function and the findings of abnormal cytology may strengthen or confirm the diagnosis of cancer, but most of these tests are not readily available to physicians at large and in most hospitals.

There are no early x-ray findings of pancreatic carcinoma, since direct visualization of the pancreas by radiographic means is not possible. The occurrence of changes due to pressure either externally or from encroachment on the surrounding structures is gen-

erally a late sign of the disease. Thus, widening of the duodenal loop or the pressure on the medial wall of the second portion of the duodenum (reverse three sign) is a relatively late manifestation. At times an ampullary carcinoma may be detected early by barium contrast studies of the duodenum. A distressing observation is that frequently patients with completely negative radiographic findings may be found at laparotomy to have a widely disseminated carcinoma.

Surgical Observations

Exploratory laparotomy may not readily solve the problem of diagnosis and treatment. Despite the freedom with which laparotomy permits one to inspect, palpate, and biopsy the questionable areas, the diagnosis may be in doubt and the surgeon be compelled to proceed on a presumptive diagnosis.

Biliary Structures

Carcinoma is most likely the underlying cause of biliary obstruction when there is a distended but thin-walled common duct and gallbladder. The duodenum and pancreas should be mobilized to permit palpation of the common duct and head of the pancreas. A systematic examination including multiple biopsies and frozen-section microscopic examinations is made to determine if the tumor has spread outside the pancreas. The lesser omental bursa is opened and biopsy taken of the lymph nodes surrounding the pancreas and in the area of the porta hepatis and root of the mesentery. Any tumor involvement in these areas precludes resection. The duodenum is mobilized (Kocher maneuver)* and the duodenum and pancreatic head reflected to the left to permit examination of the portal vein and superior mesenteric artery. Any involvement of the major vessels precludes resection. At times detection of vessel involvement may be found only after operation has progressed to the point where it must be continued, a situation to be avoided if possible.

The Duodenum

An ampullary carcinoma may be palpable as a mass through the duodenal wall; how-

*See Test Your Word Score Page 221.

ever, at times a small ampullary carcinoma will be detectable only upon opening the duodenum because, unlike pancreatic carcinomas, an early ampullary lesion tends to be soft and is difficult to detect through an intact bowel wall. On occasion it may be difficult to determine if the lesion is in the terminal common duct, ampulla, or the head of the pancreas. The common duct is explored to rule out impaction or erosion of stone into the intrapancreatic portion of the common duct. Here a cholangiogram may prove helpful.

Operative Procedures

Few take issue with the practice of taking a biopsy of an ampullary lesion; but when there is a mass in the pancreas, opinion is divided as to whether one should establish a positive tissue diagnosis before proceeding with pancreaticoduodenectomy or to proceed on the gross findings only.

Biopsy

Objections to biopsy of the lesion are that the carcinoma may be disseminated; that complications such as leakage of pancreatic juice may occur should resection not be done, and finally that multiple negative biopsies cannot be relied upon with absolute certainty that there is no carcinoma. Those who insist upon a positive biopsy contend that the magnitude of the operation of pancreaticoduodenal resection should not be undertaken without a tissue diagnosis. In general, those who have had the widest experience with pancreatic surgery tend to proceed on the gross findings only, but they recognize that there is a chance that pancreaticoduodenectomy may be performed for a benign lesion.

In Orr's review in 1952 he found five instances of pancreaticoduodenectomy for what proved to be a benign lesion.⁵ Three of these patients died as a result of the operation. At the Lahey Clinic, where biopsy was done infrequently, there were six instances of pancreaticoduodenal resection for a benign lesion among 216 operations.⁶ Carlson⁷ reported that the incidence of mistaken diagnosis of carcinoma ranged from 10 to 19%. The preferred method of biopsy is a trans-

duodenal needle biopsy, as it avoids leakage of pancreatic juice into the peritoneal cavity. The biopsy needle is directed at the central portion of the mass since the peripheral induration is usually due to pancreatitis.

Pancreaticoduodenectomy

The operative steps in pancreaticoduodenectomy are now quite well standardized. The one-stage operation is preferable and consists of subtotal pancreatectomy, total duodenectomy, removal of the gallbladder and distal one half or more of the common duct, hemigastrectomy and vagotomy. Reconstruction consists of a pancreaticojejunostomy, choledochojejunostomy, and gastrojejunostomy. Whenever possible, the pancreaticojejunostomy is made with a mucosa-to-mucosa suture of the pancreatic duct to the jejunal mucosa; but when this is not possible, implantation of the transected pancreas into the jejunum, as described by Waugh,⁸ is felt to give added protection against pancreatic juice leakage, a complication dreaded by all surgeons.

Experience at the Minneapolis Veterans Hospital

The records of 119 patients, all male, operated upon during a 14-year period (1950-1964) for carcinoma of the pancreas and periampullary area were reviewed (Table 1). An accurate determination of the location of the tumor could not be made in all instances, but carcinoma was in the head of the pancreas in 86 patients, in the ampulla in 18, in the body of the pancreas in 18, and in the terminal common duct in one (Table 1). All the tumors were adenocarcinomas.

Palliative Procedures

The operative procedures are listed in Table 2. Laparotomy and biopsy only was done in 32 patients. These patients had extensive liver metastases, carcinomatosis or infiltration of the porta hepatis; hence even a palliative procedure appeared contraindicated. Palliative procedures in 49 patients consisted of cholecysto or choledochojejunostomy and gastrojejunostomy where obstruction appeared imminent. Twenty-one of these patients deteriorated rapidly and were dead within two weeks. Sixty patients recovered from the operation and survived a mean period of 3.2 months. The longest survivor lived 11 months.

Pancreaticoduodenectomy

Pancreaticoduodenectomy was done in 38

of the 119 patients. The procedures consisted of 25 resections for carcinoma of the head of the pancreas, 10 for carcinoma of the ampulla, two for lesions of the body and one for carcinoma of the distal common bile duct involving the duodenum and pancreas (Table 3). The average age of the patients with carcinoma of the head of the pancreas was 60 years. Sixteen had significant pain as a presenting complaint, 24 had jaundice, and 21 had weight loss ranging from 10 to 60 pounds. There were five postoperative deaths (20 per cent). The average postoperative survival was 12 months. Three of the longest survivals were as follows: one patient survived 41 months but died at the age of 58 with recurrence of cancer; the second patient is alive at 36 months at the age of 64 and in fairly good health except for emphysema, and the third patient is alive and well at 24 months. In the patient still alive at 36 months there was carcinoma in a lymph node adjacent to the pancreas and perineural invasion with carcinoma. Two patients in this group had total pancreatectomy. One patient, in addition to the total pancreatectomy, had a portocaval shunt because of vein involvement. He survived ten months and died of recurrence. Fifteen patients had carcinoma in the lymph nodes and seven had perineural invasion with carcinoma.

Ten patients had pancreaticoduodenec-

Pancreaticoduodenectomy*

Location of Tumor	# of Cases	Operative Mortality	Average Survival	Longest Survivals
Head	25	5 (20%)	12 months	One survived 41 mo., died of recurrence; one alive at 36 mo., and one alive at 24 mo.
Ampulla	10	0	40 months	One each alive at 28 mo. and 7 yrs. One died 7 yrs. postoperatively at age 74 of cerebral vascular accident, and one 9 yrs. postoperatively at age 74 of coronary heart disease. Autopsy in both patients showed no recurrent tumor.
Body	2	1 (50%)	1 died at 6 wks. 1 died at 15 mo.	
Terminal common bile duct	1	0	17 months	
Total	38	6 (15%)		

*Total pancreatectomy was performed twice, one for a lesion in the head, one for an ampullary carcinoma. All others are subtotal resections.

tomy for carcinoma of the ampulla of Vater. There was no postoperative death. The average survival period was 40 months. At the time of this report one patient is alive at 28 months and one at seven years, both in good health. One patient died seven years postoperatively at the age of 74 because of cerebral vascular accident and another nine years postoperatively at age 74 of coronary heart disease. Autopsy showed no tumor in either patient. Another patient died two years after a previous ampullectomy followed by recurrence of carcinoma.

Carcinoma of the body of the pancreas was resected in two patients. One patient survived 15 months and died of recurrence. At the time of the operation there were metastases to the regional lymph nodes. The second patient, aged 45, had a portacaval shunt along with the pancreaticoduodenectomy. He expired six weeks postoperatively of peritonitis and renal shutdown. An au-

topsy showed multiple metastases to the liver.

Postoperative Complications

Postoperative complications after pancreaticoduodenectomy are listed in Table 4. Complications occurred in 10 of the 20 patients who survived pancreaticoduodenectomy for carcinoma of the head of the pancreas. There were three instances of severe postoperative bleeding, two of subphrenic abscesses requiring drainage, and three of infection of the abdominal wound requiring drainage. One patient had a wound hematoma requiring reoperation, and another, listed as having a subphrenic abscess, also required prolonged bile drainage.

Postoperative complications in the group in whom pancreaticoduodenectomy was done for ampullary carcinoma consisted of two instances of wound infection requiring drainage and one case of massive gastric hemorrhage 23 days postoperatively, which required conversion of a previous 40% stomach resection to 75% resection because of a gastrojejunal ulcer. This patient survived nine years and died at age 74 of coronary heart disease.

The causes for the six postoperative deaths were as follows: three patients had severe hemorrhage; one patient had bleeding, renal shutdown and peritonitis, and died 31 days postoperatively; another had bile leakage, peritonitis and uremia, and died on the thirteenth postoperative day, and the sixth patient died of peritonitis six weeks postoperatively (Table 5).

Discussion

In presenting our own experience, separation of carcinoma of the pancreas from carcinoma of the ampulla of Vater was made because the true picture of carcinoma of the pancreas cannot be presented when both types are grouped together. Preoperatively, however, it is of only academic interest to attempt to distinguish the origin of the lesion; similarly at operation it is not absolutely essential that one know the exact origin, since the operative maneuvers are basically identical. However, in evaluating

TABLE 4
Nonfatal Postoperative Complication

	Survivors	No. of Complications	Type
Ca head	20	10 (50%)	3 severe postoperative bleeding, 2 subphrenic abscesses, 3 infected abdominal wounds, 1 wound hematoma, 1 prolonged bile drainage
Ca ampulla	10	3 (33%)	2 wound infections, 1 hemorrhage from gastrojejunal ulcer treated by 75% gastrectomy
Ca body	1	0	
Ca terminal common duct	1	0	

TABLE 5
Causes of Postoperative Death

	No. of Patients	Postoperative Deaths	Cause of Death
Ca head	25	5 (20%)	3 severe hemorrhage 1 hemorrhage and uremia 1 bile leakage, peritonitis, uremia
Ca body	2	1 (50%)	Peritonitis

the results it is essential to separate the two types, because identifying them both as carcinoma of the pancreas presents a too favorable view of actual carcinoma of the pancreas and a relatively unfavorable picture of carcinoma of the ampulla.

Even the surgeon most experienced in pancreatic surgery cannot tell for certain the origin of the tumor of the head of the pancreas, the terminal common duct and the ampulla of Vater. In the absence of contraindications to pancreaticoduodenectomy, the operation should nevertheless be performed; because if, on the basis of a gloomy outlook for carcinoma of the pancreas, one were to do only a palliative procedure, he would deny the patient who has carcinoma of the ampulla of Vater an opportunity for cure. This point is emphasized by all who have extensive experience in pancreatic surgery.⁶

In our own experience, because of the large number of surgeons performing the operation, and generally most of these younger men on the staff, no one was able to accumulate any significant experience with pancreatic surgery. However, it is gratifying to find that the mortality rate was no higher than that reported by other groups. In evaluating the operative reports it was readily apparent that because of the surgeon's inexperience it was only rarely that he proceeded without a tissue diagnosis. Even if the tissue diagnosis had not been made, biopsy had been taken. The operability rate of 31% appears too high. Records show that in five patient after the operation was well under way, spread of carcinoma was found but pancreaticoduodenectomy was carried to completion.

Several of the recent reports are quite instructive in this respect. In 1958 Porter⁹ reported on the complete experience of treatment of carcinoma of the pancreas from Columbia University. There were 259 histologically proven diagnoses of carcinoma. It was found that in the cases of 38 patients who had had pancreatic resection, even the most experienced surgeon could not be trusted in his interpretation of the origin of the tumor. There was no five-year survival in

adenocarcinoma of the pancreas. Based on the surgeons' program of detailed examination of the nodes surrounding the pancreas and of the regions where early spread occurs it was found that the operability rate for carcinoma of the pancreas fell from 21.1% to only 6.8%. In contrast, the operability rate for carcinoma of the ampulla of Vater fell from 70% to 66.6%.

Glenn³ reported on a thirty-year experience from the New York Hospital and concluded that in his and his colleagues' hands carcinoma of the pancreas was an incurable disease. Of 25 patients who underwent radical pancreaticoduodenectomy four lived more than two years, one of these surviving nine years and then dying of recurrent carcinoma. Despite the poor results Glenn concluded that the procedure was worth continuing, because no patient survived a full two years following any procedure other than pancreaticoduodenectomy.

Other more recent results are reported by Monge, Judd and Gage from the Mayo Clinic,¹⁰ where eight patients survived five years after pancreaticoduodenectomy for ductal carcinoma, a five-year survival rate of 14.3%. Out of 46 patients 18 patients were still living five years after excision of carcinoma of the ampulla of Vater, a 39.1% five-year survival.

Conclusions

Surgical cure of pancreatic carcinoma is difficult to attain. By the time the so-called classical symptoms appear, 80 to 90% of the cases have passed the stage where complete excision is possible. Most reported series including our own have no five-year survival; however, 14% five-year survival attained by one group suggests that the operation should be continued in selected cases. All agree that longer survival occurs in the group treated by pancreaticoduodenectomy rather than by a palliative procedure, although one might argue that selection automatically occurs in such instances.

Carcinoma of the ampulla of Vater and of the pancreas behave differently. Five-year survivals of over 30% are reported by others, and similarly in our group, three of ten patients lived over five years. In two late

deaths (7 and 9 years postoperatively) autopsy revealed no recurrent tumor. These results alone justify continuation of radical pancreaticoduodenectomy for resectable le-

sions of the head of the pancreas since one cannot always separate with certainty lesions of the ampulla of Vater from some lesions of the head of the pancreas.

Medical Men and Music*

Eighteenth century William Withering (1741-1799) of Birmingham, pioneer in the use of digitalis for heart disease, played both the harpsichord and the flute, and Edward Jenner (1749-1823), pathological anatomist, performed on the flute and the violin.

For vocal music Sir Robert Christison (1797-1882) of Edinburgh, author of the first work on toxicology, distinguished himself.

"As a singer, both as a soloist and in part-songs, Sir Robert took a high place among the amateur musicians of Edinburgh. He was gifted with a bass voice of unusual power and good quality; and although he never had time to take lessons, constant practice in quartet singing and in small musical societies brought his voice to some degree of cultivation. . . . Sir Robert's voice retained much of its power and quality till he was past seventy, and he did not give up taking an occasional share in part-singing for several years afterwards. The last occasion on which he joined in anything of the kind was on the eighty-third anniversary of his birth, when he took the bass part of Bishop's well-known 'Mynheer Van Dunck'."**

In nineteenth century Germany Friedrich Henle (1809-1885), eminent histologist, performed so well on the violin, viola, and violoncello that he could join any extemporaneously arranged string quartet and acquit himself creditably. And Albert Billroth (1829-1894), noted surgeon, enjoyed music both passively through appreciation and actively through performance. In rhapsodizing on the rendition of "Manfred" he said:

"Manfred! Ah, but you should have heard and seen it! Reflections are useless, it is indescribable; full-blooded poetry and full-blooded music! It is stunning in a sensuous way; one dreams, one floats in the soft air without effort."**

Of his own keyboard facility he said:

"At this moment my fingers tremble after playing Bach for an hour. That is a tremendous tax for the fingers, for not only each measure, but the whole must be shaped forth like a Gothic stone structure, tall and great. This morning I have given myself up to this music with a kind of passion."**

Management of Head Injuries

CHARLES B. WILSON, M.D.*
HORACE A. NORRELL, JR., M.D.*
Lexington, Kentucky

THE FREQUENCY of head injuries from vehicular accidents justifies repeated emphasis of therapeutic principles underlying care of accident victims. The great majority of head injuries can and should be managed in community hospitals by nonspecialists in neurosurgery. However, recognition and initial care of those few cases which should be transported to a neurosurgeon is no less important. This paper emphasizes aspects of closed head injuries which we believe are basic to proper management.

The subject has been divided into four phases to present a systematic, step-wise approach to the head-injured patient. Associated injuries and management of the head injury will be described accordingly.

Emergency Treatment

Airway

An adequate airway must be secured and maintained before anything else is done. No injury takes precedence over the airway and no other measures should be undertaken until an airway has been established. This may require nothing more than positioning; but often, particularly in the seriously injured patient, tracheostomy is the wisest course. Tracheostomy is rarely done unnecessarily and is best done selectively. A head injury itself does not cause tachypnea, cyanosis or stertorous** breathing. Brief anoxia may produce irreversible cerebral damage in critical situations, and the airway must always receive first priority.

Control Bleeding

Active bleeding must be stopped, which generally means securing a lacerated major artery in the face, neck or extremities. The

*From the Department of Surgery, Division of Neurosurgery, University of Kentucky College of Medicine, Lexington.

Supported in part by the Dewey Daniel Fund and the Fred Rankin Fund for Surgical Research.

**See Test Your Word Score Page 221.

bleeding scalp can be temporarily controlled by firm pressure with the fingertips or by a firm dressing. Persistent bleeding from the scalp is managed by placing a hemostat on the galea and turning it over the scalp edge. In practice, scalp bleeding is seldom more than a troublesome ooze which can be stopped by a firmly applied, sterile dressing.

Treatment of Shock

The third immediate problem is shock, which should be treated without regard for the head injury. Cerebral concussion may be accompanied by a "shock-like" state, the duration of which is a matter of minutes. With this unimportant exception, head injury alone never produces shock. Although considerable blood can be lost from a torn superficial temporal or occipital artery, rarely is blood loss from the scalp sufficient to be shocking. The cause must be sought in the thorax, abdomen, pelvis or extremities. In the shocked patient, administration of blood or blood substitutes is the only method of restoring the cerebral circulation. The Trendelenburg position does not improve cerebral blood flow in the hypotensive patient, and venous congestion in the head-down position is deleterious.

Evaluation and Establishment of Baselines

The History

A good history is invaluable, and facts relating to the accident should be gleaned from any witness. The patient's state of health immediately prior to the injury as well as any past history of disease of the nervous system, alcoholism, or major medical illness should be learned, if at all possible.

The Physical Examination

The general physical examination should be thorough and systematic, and even in the unconscious patient general examination should precede the neurological examination.

Vital signs will approximate normal values in uncomplicated head injuries. A rapid rise in intracranial pressure produces bradycardia, a rise in systolic blood pressure, and slowing of respiration, in that order. A deviation of vital signs from the normal range

may be due to cerebral or, more commonly, to extracerebral causes.

Very early after injury, the course of a *fracture may be delineated* accurately by an overlying ridge of local edema. Crepitus beneath the scalp may be secondary either to air forced through a laceration or to fractures into a paranasal sinus. A "doughnut hematoma" of the scalp invariably feels like a depressed fracture; but regardless of the impression gained by palpation, the diagnosis of depressed fracture should not be made without radiographic confirmation. Fractures of the facial bones and jaw do not require immediate attention, unless threatening the airway, but their presence should be determined before facial edema precludes adequate examination. The orbits and zygomas should be palpated, the maxilla rocked by traction on the upper incisors, and the lower jaw checked for dental occlusion, mobility, and crepitus. If facial edema is already present, assume the presence of facial fractures.

The ears should be examined for the presence of blood within the external canal or behind the tympanic membrane, as the finding of blood in either site indicates a *basilar skull fracture*. Ecchymosis over the mastoid tip is equally significant.

Epistaxis, in the absence of significant direct trauma to the nose, and cerebrospinal rhinorrhea indicate a basilar fracture into one of the paranasal sinuses. The treatment of basilar fractures will be considered later. Damage to the eyeball or its adnexa should be determined before periorbital edema closes the eyelids.

Local tenderness or a *displaced spinous process* may indicate a fracture of the cervical spine. A patient in coma does not resist movement of the neck, and a supple neck in the unconscious patient does not exclude a spinal injury. Evidence of trauma to the anterior cervical region should alert the examiner to the possibility of injury to the trachea and carotid artery. Direct trauma to the carotid artery can induce arterial thrombosis with infarction of the cerebral hemisphere and hemiplegia which may be

attributed mistakenly to an expanding intracranial hematoma.

Abdominal paracentesis is an invaluable diagnostic procedure and is mandatory when the cause for shock cannot be explained by other extracranial injury. Ruptured spleens appear to be notoriously common in patients with head injuries. Head injuries do not cause ileus; but thoracolumbar fractures, with or without spinal cord injury, are regularly followed by reflex paralytic ileus.

As part of the general examination, a *nasogastric tube* is passed for evacuation of the stomach contents, which makes vomiting less likely and circumvents aspiration of vomitus. Swallowed blood is usually found with extensive facial injuries and will be vomited if not removed. The nasogastric tube may be left in place and attached to low suction. An indwelling urethral catheter should be passed in all unconscious patients and in those unable to void voluntarily. Examination of the urine for blood should be carried out immediately to exclude injury to the urinary tract.

Neurologic Examination

The level of consciousness is determined by graded stimuli. Starting with commands spoken in a normal tone, stimuli of increas-

ing intensity are applied to the point of responsiveness. With minor variations, the stimulus and response will remain constant or indicate a return toward a fully conscious state during the early period of observation. The stimulus may be anything from calling the patient's name in a normal tone to firm supraorbital pressure. The response may be an opening of the eyes or purposeless shifting of position and withdrawal from pain produced by the examiner.

The state of consciousness is the most important observation, and it must be recorded for future reference. The following terms describe the level of consciousness: *coma*: unresponsive to all stimuli; *areflexic** except for a direct tracheal cough reflex; *semi-coma*: responsive to noxious stimuli; response may be purposeful, but unable to carry out commands; *stuporous*: confused, faulty recognition; may carry out simple command after coaxing; *sleepy*: easily aroused.

The pupils are checked for equality and reaction to light. Minor inequalities may come and go and, if transient, are unimportant. Direct blows to the eye produce traumatic mydriasis which may persist for hours or days. Sympathetic involvement is uncommon, but a Horner's syndrome may account for pupillary inequality. With these exceptions, *unilateral dilatation of a pupil* pre-

Figure 1

**See Test Your Word Score Page 221.

sumes a mass intracranial lesion requiring surgical intervention. Bilateral dilated and fixed pupils indicate a hopeless situation; we know of no patient with a neurosurgical condition who has ever recovered after manifesting this ominous sign. Do not use mydriatics; the information gained by funduscopic examination does not warrant loss of the important pupillary reaction.

Cerebral hemisphere function can be assessed by observing spontaneous or induced movements of the extremities. Hemiparesis evident immediately following injury is most often due to cerebral contusion, whereas hemiparesis appearing later is assumed to be caused by an intracranial hematoma. Speech must be evaluated in keeping with the patient's conscious state. A minor aphasic disturbance may be a valuable initial observation.

Reflex activity has the advantage of objectivity and the usual reflexes should be tested. Bilateral Babinski responses are not uncommon in patients with head injury or subarachnoid hemorrhage, and in the post-seizure state. The early presence of decerebrate or decorticate rigidity indicates initial injury to the brain stem. The late appearance of these responses is due to herniation of the brain with secondary brain stem compression and indicates a dynamic process requiring investigation.

Damage to the *optic or oculomotor nerves* can be determined by direct and consensual pupillary reactions to light. The extra-ocular muscles are not examined individually, but the range and nature of spontaneous and induced eye movements should be recorded. Eye movements are best elicited by rapidly turning the head, first to one side and then to the other. Disconjugate eye movements indicate either deep coma or primary injury to the brainstem with involvement of the pathways connecting the nuclei of III and VI. The facial nerve is easily tested. Peripheral facial palsy occurs with basilar fractures into the ear and may be immediate or delayed in appearance. In the presence of facial weakness, the cornea may require protection by temporary closure of the eyelids with a strip of adhesive which can be re-

moved periodically for inspection of the pupil.

Roentgenograms

Skull roentgenograms should be taken only after emergency treatment. The value of early examination is limited, but certain findings may be of great importance. Properly positioned films permit recognition of pineal shift, fracture into an air-containing paranasal sinus, fracture across the middle meningeal groove or a major venous sinus, the presence and extent of depressed fractures, and compound fractures not suspected by physical examination.

Every unconscious patient should have anteroposterior and lateral views of the cervical spine. Otherwise, cervical fractures may go undetected and the patient may suffer additional damage to the spinal cord before recognition and proper treatment of the spinal injury.

Lumbar Puncture

We do not utilize lumbar puncture in the management of acute head injuries. Lumbar puncture should be performed if meningitis is suspected, a situation which may arise several days after the injury. In addition it may be of some value in the comatose patient with no history, in whom a head injury must be excluded.

Management of Head Injury

Provided that there is historical, external, or x-ray evidence of injury to the head, a patient should be managed as a head-injury case. This statement applies particularly to alcoholics, epileptics, and "strokes."

A trivial head injury can become a fatal head injury. Every hour, more or less frequently, depending upon the patient's condition, the following observations should be made and recorded on a separate sheet with orders to notify the physician if:

(1) Pupils originally equal become unequal. (This may be impractical in understaffed areas.)

(2) The neurologic status deteriorates. (By deterioration is meant the development of new neurologic signs, a depression of the

state of consciousness, or unilateral pupillary dilatation.)

(3) Pulse rate becomes less than 60 or greater than 130.

(4) Respiratory rate becomes less than 16 or greater than 34 (or irregular).

(5) Systolic blood pressure becomes less than 100 or greater than 150 (in the young adult).

Observation is understandable when one considers the purpose and limitations of neurosurgical intervention. An operation can relieve increased pressure and terminate compression of contiguous structures produced by a hematoma. Fortunately, most hematomas develop slowly and announce themselves by producing gradual deterioration in a patient's condition; therefore, if a baseline is established soon after the injury, failure to improve or regression from the baseline status can be recognized. On the basis of serial observations, any deterioration in a patient's neurologic status is an indication for excluding an expanding hematoma as the cause.

Care of the Unconscious Patient

Aspiration of vomitus is often fatal and vomiting may be delayed until the second or third day, especially when blood is present in the stomach. Good practice in the unconscious patient is insertion of a nasogastric tube attached to suction. The patient should be turned side to side every hour. The flat supine position is best for examination, but should not be maintained because of the risk of aspiration. In the absence of pulmonary complications and shock, the head is best kept elevated 20-30 degrees to encourage venous return from the head.

The cornea should be protected from drying or abrasion. A strip of scotch tape over the lid is adequate. Hyperpyrexia must be treated promptly because it exhausts the patient's reserves and adversely affects the damaged brain. A temperature of 101° or above should be treated vigorously, and specific directions should be written for measures to reduce it. Hyperpyrexia, often delayed in onset for 12 to 36 hours, is best controlled by aspirin and sponging. Tube

feedings may be started at the end of 48 hours if the patient has had a tracheostomy, has not vomited, and if gastric fluid recovered by continuous suction is not excessive.

Intravenous fluids should allow a daily urinary output of about 1,000 cc. A small number of severely injured patients will retain or lose salt because of hypothalamic damage. Blood chemistries should be determined at least every other day for one week. Deliberate dehydration does not reduce cerebral edema and has no place in the management of acute head trauma. An indwelling urinary catheter lessens the nursing problem and permits accurate determination of urinary output in the unconscious or uncooperative patient.

Special Problems

Convulsive seizures may occur in patients with head injuries soon after injury. Many early seizures are focal, and characteristics of the seizure often indicate the site of cerebral irritation. Because a single seizure may progress into status epilepticus, convulsions must be treated vigorously. An early seizure does not indicate the presence of an intracranial hematoma. Seizures are best managed with phenobarbital, paraldehyde and dilantin, I.V. or I.M., depending upon the urgency of the situation. Sodium amytal and pentobarbital are not anticonvulsant drugs and should not be used for this purpose. Barbiturates are used with caution because of their respiratory depressant effect. An unobserved seizure may produce a confusing situation. Seizures produce hypoxia, adversely affect the head-injured patient, and must be controlled promptly.

The incidence of *traumatic diabetes insipidus* is low. Polyuria may appear early or late, usually several days after the accident, and characteristically commences with great suddenness. The use of aqueous pitressin simplifies fluid replacement. Headache may become a complaint with return of consciousness. The usual headache is similar to that which sometimes follows lumbar puncture. Persistent severe headache is unusual and warrants spinal tap if continued into the second week post injury. Subarachnoid

hemorrhage also produces headache which generally subsides in three to four days. The value of repeated spinal taps for relief of headache is questionable.

Restlessness to an extreme degree during the acute stage is uncommon, and if present its cause should be sought in a full bladder, an unrecognized fracture, extreme meningismus from subarachnoid hemorrhage, delirium tremens, or frontal lobe injury. Wrist and ankle restraints often aggravate the situation and should be used only as a last resort. Side rails and an attendant are preferable to any mechanical restraint. Sedation during the acute phase of injury depresses respiration and the level of consciousness, and is contraindicated, even in minor head injuries.

Basilar skull fractures into the middle ear or paranasal air sinuses often accompany severe head injuries, although they may follow relatively minor trauma. Fractures involving the ear are readily detected by otoscopic examination if the tympanic membrane is intact, or by the observation of blood or cerebrospinal fluid draining from the ear. Fractures into the frontal and ethmoid sinuses should be suspected in all patients with facial injuries. The diagnosis is established by observing cerebrospinal fluid rhinorrhea, remembering that in the supine unconscious patient this may go undetected. Fractures into the frontal and ethmoid sinuses are usually visible on roentgenograms. All basilar skull fractures are compound fractures by virtue of communication through a torn mucous membrane into an air-containing cavity. Treatment of basilar skull fractures requires therapeutic antibiotic coverage for at least seven days, and longer if leakage of cerebrospinal fluid persists. The conscious patient with cerebrospinal fluid rhinorrhea should be cautioned against nose-blowing.

Carotid-cavernous sinus fistulas may appear immediately, or as late as several weeks after injury. The fistula results from a tear in the carotid artery as it passes through the cavernous sinus and is characterized by pulsating exophthalmos and a cranial and orbital bruit. The condition does not require

emergency treatment, although most fistulas persist without surgical intervention.

Indications for Surgery

Compound Fracture

Open head wounds are injuries in which the intracranial contents are in open communication with the air through either scalp or skin. These are compound fractures, and treatment involves debridement and closure of the wound. Experience in World War II taught that patients with open wounds, unless fatally injured, do not deteriorate rapidly. They tolerate transfer by ambulance or by air to a hospital equipped for major cranial surgery. Compound wounds should be carefully debrided with water-tight reapproximation of the dura and accurate closure of the scalp without drainage.

Extensive compound wounds should be transferred to a neurosurgical center. Emergency treatment of the cranial wound should be limited to the application of a sterile dressing over the wound. Rarely will active bleeding from the scalp or exposed cerebral vessels constitute a problem. No attempt should be made to remove clotted blood or exposed brain which will only activate bleeding and introduce further contamination. The initial surgery should be definitive; nothing beyond the application of sterile dressing is indicated prior to transfer. Other emergency measures directed at establishing an airway, splinting long-bone fractures, and combating shock should be implemented when the patient is initially treated. Definitive debridement can be delayed up to 24-48 hours without a significantly increased risk of infection, provided prophylactic antibiotic therapy is started promptly.

Depressed Fractures

Depressed skull fractures with an intact scalp are treated as closed head injuries. The underlying brain is damaged at the moment of impact, and the continued presence of the depressed bone is not detrimental if the degree of depression is slight. Almost all depressed fractures should be corrected surgically, but rarely do they constitute an emergency.

Intracranial Hematomas

Subarachnoid hemorrhage, common even in trivial head injuries, produces meningeal irritation but requires no treatment and will not be discussed. Blood in significant quantity can collect on each side of the dura mater or within the brain. The former, extradural and subdural hematomas, lie on the brain surface and are accessible through trephine openings in the skull. The latter, intracerebral hematomas, are uncommon in the absence of depressed skull fractures, and the diagnosis is difficult to establish without special studies. Surface hematomas can be diagnosed and treated through burr holes. The remainder of the discussion will be confined to subdural and extradural hematomas.

Extradural Hemorrhage

Extradural hemorrhage is the one true neurosurgical emergency. A typical case will have minor trauma to one temple followed by a lucid interval of one to six hours, and then manifest signs of rapidly progressive compression of one cerebral hemisphere. A fracture crossing the middle meningeal groove is nearly always present. After an initial complaint of headache, weakness of one side of the body quickly appears with somnolence deepening to stupor and dilatation of the pupil on the side of the hematoma. The evolution of extra-dural hematomas is rapid because blood under arterial pressure is forced into the extradural compartment from a torn middle meningeal artery. Compression of the brain must be relieved immediately. Time does not permit transfer of the patient to another hospital and the blood clot must be evacuated without delay. Such a patient is probably the only one whose life will be saved by surgery performed in the first few hours after injury. The objective of surgery is an opening in the skull which will allow extrusion of the clot. The hematoma usually underlies the temporal fracture, and the first burr hole should be made at the fracture site. After enlarging the burr hole with rongeurs, the torn meningeal artery can be coagulated, clipped, or transfixed with sutures. If these measures fail, the bleeding will be considerably dimin-

ished by ligation of the external carotid artery in the neck. The surgeon on the spot must operate then and there, once the diagnosis is suggested. A neurosurgeon may be summoned by phone, but evacuation of the hematoma should not be delayed until he arrives. (See appendix for operative technique.)

Subdural Hemorrhage

Subdural hemorrhage can also be acute, with rapid deterioration necessitating surgery within the first 48 hours after injury. The bleeding is arterial but is caused by laceration of the brain with tearing of cerebral arteries. Brain damage is characteristically severe and blood in the subdural space is coincidental. The lacerated and contused brain swells rapidly, and evacuation of the small subdural hematoma accomplishes little or nothing. Mortality with acute subdural hematomas exceeds 90%. Rarely, acute subdural hematomas may develop from a torn venous sinus or Sylvian vein without significant damage to the brain. This latter hematoma mimics an epidural hematoma and is treated by the same principles.

Chronic subdural hematomas manifest themselves three to 12 weeks after injury. Minor and often forgotten trauma tears a vein bridging from the cortex to the superior sagittal sinus, and resultant venous bleeding is slow. Encapsulation and secondary enlargement produce the delayed onset of signs and symptoms. Drainage through exploratory burr holes is curative if brainstem compression has not reached the state of irreversibility.

Subacute subdural hematomas are intermediate between acute and chronic hematomas. Headache, progressive somnolence, and a generally unfavorable course prompt investigation at some time beyond the third day post injury. The outlook is favorable for satisfactory recovery.

Subdural Hygroma

Sometimes, particularly with a subacute evolution, one encounters a subdural hygroma rather than a hematoma. A hygroma consists of xanthochromic cerebrospinal fluid

probably resulting from a tear in the arachnoid. Clinically, hygromas cannot be differentiated from hematomas and they respond to drainage through burr holes.

Carotid angiography is being employed with increasing frequency as an accurate investigative study. Bilateral carotid angiograms permit localization of hematomas as well as demonstration of unsuspected pathology, but carotid angiography is a procedure for the expert because interpretation may be difficult.

The use of corticosteroids, hypothermia and hypertonic urea to decrease cerebral edema may have a place in the treatment of closed head injuries. Hypothermia requires equipment and nursing care available only in certain centers. Urea should not be used without excluding a mass lesion by burr holes or angiography; even then, its value is quite limited.

Emergency Surgery

Release Hematoma

Any hospital with facilities for major surgery should be equipped to perform burr holes for an epidural hematoma. In addition to the standard surgical instruments the following instruments should be available:

Hudson brace
McKenzie perforator
Cushing burr
periosteal elevator
mastoid retractor or self-retaining tissue retractor
angular double-action rongeur
Frazier suction tip
bone wax
(a Bovie unit is helpful but not essential)

Surgical Procedure

The skin incision is vertically placed 1½ inches behind the orbital process of the frontal bone, extending from the superior extent of the temporalis muscle to the zygomatic arch (Figure 1).

The temporalis muscle is stripped bilaterally from its attachment to the temporal bone and the muscle retracted with a self-retaining retractor.

A burr hole made in the thin temporal bone directly above the zygomatic arch is enlarged with a rongeur to expose the middle meningeal artery and the hematoma. The hematoma can be evacuated using forceps and the suction tip. Bleeding is controlled with electrocautery, ligatures and bone wax; diffuse oozing from dura can be controlled with fibrin foam and gentle pressure. If bleeding cannot be stopped, the wound can be packed and the patient transferred to a neurosurgical center.

If no hematoma is present at the first site, a second opening should be made over any existing fracture line.

Summary

The provision of an adequate airway, recognition and treatment of associated injuries, and maintenance of physiologic function in an unconscious patient constitute the basic management of closed head injuries. Regression from initial baselines indicates a dynamic process which warrants investigation to exclude or establish the existence of a treatable lesion.

Eyes are compacted powers; they are an index of vision; they see and refer us to greater seeing. Nor has the stomach a less noble office. It digests food; that is, in its own particular method, it deals with the nourishment offered by the universe. It is the physical formula of that health which destroys certain elements — the bacteria which harmfully approach us. By it we learn to consume; by it therefore to be, in turn, consumed. So even with those poor despised things, the buttocks. There is no seated figure, no image of any seated figure, which does not rely on them for its strength and balance. They are at the bottom of the sober dignity of judges; the grace of a throned woman; the hierarchical session of the Pope himself reposes on them. — Charles Williams

Percutaneous Non-Catheter Retrograde Brachial Arteriography*

Use
of the
Amplatz
Needle

DAVID SWEET, M.D.**
San Bernardino, California
J. T. GRISMER, M.D.†
Minneapolis, Minnesota

 BSTRUCTIVE VASCULAR lesions in the brachiocephalic arterial network may produce incapacitating symptoms in the patient who has cerebral-vascular insufficiency. Satisfactory surgical correction and re-establishment of arterial flow is possible for many of the extracranial vascular obstructions. Precise delineation of the extracranial and intracerebral arteries is a necessity for such surgical procedures. The diagnostic procedure should not increase the risk to these ill patients.

Percutaneous non-catheter retrograde brachial arteriography is a safe and reliable method to visualize three of the four major arteries and their branches in the neck and brain.^{1,2} By retrograde injection of the right brachial artery the contrast material will fill the right subclavian, the right vertebral, and the right carotid arterial systems. This includes excellent visualization of the basilar artery, the carotid siphon, and the major cerebral branches. Not only is the bifurcation of the right carotid artery well documented, but in 15% of the patients the cervical portion of the left carotid artery will be visualized, as the innominate artery gives common origin to both carotid vessels. Injection of the left brachial artery fills the left vertebral artery, the basilar artery, and its branches. The degree of visualization of these vessels is dependent upon variations in the natural anatomy, the disease processes, and the amount and rapidity of injection of the radiopaque medium.

In their descriptions other authors have reported the use of a thin-wall 17-gauge steel indwelling brachial needle through which the injection is made. A slight variation of

the described techniques has been utilized at our laboratory. We believe that the use of an Amplatz teflon catheter-needle is less likely to produce complications with high pressure injection of contrast material and increases the safety of the procedure.³

The Amplatz catheter-needle consists of an outer flexible teflon sheath, a middle blunt steel needle, and an inner ultra-sharp pointed metal obturator (Figure 1). The teflon catheter has a standard Luer-lock fitting for secure attachment to the pressure injector connections.

Technique

Our experience with this technique has demonstrated its low risk even in the acutely ill patient. Because of this result, we would like to describe in more detail certain facets of the procedure which have proven helpful to the patient and to us so that consistent optimum x-ray visualization of the vessels is secured.

Preoperative Preparation

On the day prior to the event the surgeon

Fig. 1—The Amplatz needle and its component parts. A. Stylus tip of the assembled needle unit. B. Tapered teflon catheter and connector. C. Blunt hollow inner metal cannula. D. Solid inner stylus. E. Position of introduction into the brachial artery medial to the biceps tendon.

explains the salient points to the patient so that he has a clear understanding. (Obviously, this is not possible in certain individuals, as illness precludes understanding.) Preoperatively the patient receives an anti-histamine three hours before, a barbiturate two hours before, and an analgesic and atropine one hour before the injection. He is then placed on the X-ray table next to the bi-plane rapid film-changer unit. Scout x-ray films for proper position and technique are processed.

Introducing the Needle

During this interval the patient's arm is abducted and extended, a blood-pressure cuff placed on the forearm, and the antecubital and elbow area prepared and isolated with sterile drapes. The brachial artery is palpated. The skin puncture site, the V of the muscle junction in the forearm (Figure 2), is infiltrated with a local anesthetic as is the area of the artery. The skin is first "stabbed" with a No. 15 scalpel blade and an 18 or 19 Amplatz needle introduced through the stab wound and guided into and usually through the brachial artery.

The obturator is removed and the steel-teflon unit slowly withdrawn, slightly depressing the shaft. Entrance into the arterial lumen is signaled by a sudden pulsatile flow of blood and often a definite palpable "click." The teflon sleeve is advanced gently into the vessel lumen as the inner cannula is removed. Occasionally the teflon sleeve cannot be advanced without the aid of a coiled wire guide.

The Injection

Retrograde injection of contrast medium is made only if there is good pulsatile blood flow through the needle. The teflon catheter is connected to a CO₂ pressurized injector-syringe for rapid instillation of 40-50 ml. of 60% methylgluamine diatrizoate. The blood pressure cuff about the forearm is elevated to 200 mm. Hg. just before and decompressed immediately after the injection. A special person is assigned to this cuff inflation-decompression to avoid inadvertent maintenance of inflation and ischemic damage to the hand. The teflon catheter is disconnected from the injector and patency main-

tained by saline flushing during the processing of the X-ray films.

Only when satisfactory visualization of the vessels has been obtained does the operator remove the intra-arterial catheter. It has not been uncommon to make several injections with extreme postural changes of the patient's head in order to adequately see certain anatomical areas, especially the ver-

tebral artery origin. The right brachial artery is usually injected first and the left brachial artery, second.

Safety Measures

1. All patients are seen in consultation with a neurologist. Angiograms are not done if there is not unanimous agreement.

2. The radiologist determines the type and

Fig. 2 — Obstruction of origin of right vertebral artery. No filling of the right carotid artery occurs when this patient rotated his head to the right in the right posterior oblique position.

Fig. 3 — Obstruction of the internal carotid artery at the bifurcation. The vertebral artery is tortuous but non-obstructed.

amount of contrast media and injection pressure. Consultative pre-procedure discussion defines the pertinent vessels to be studied.*

3. The total amount of contrast media injected at one sitting is limited to prevent secondary brain injury; only in rare circumstance will this amount be exceeded. We feel that the patient should be returned for further studies on another day.

4. If the extracranial vessels are "normal," intracerebral arterial studies are usually recommended.

5. The left carotid system is visualized by direct percutaneous puncture or retrograde aortic arch injection.

6. Papaverine 15-30 mgm. is injected prior to removal of the needle.

*The authors are grateful to Drs. S. Feinberg and M. Goldberg for their valuable help.

Results

This technique has been utilized in 55 studies. Examples are demonstrated (Figure 3). There has been no adverse effect in any patient. There has been no nerve injury or ischemic sequela in any extremity. One patient had an absent radial pulse post study. In a few patients the procedure was terminated because of inability to satisfactorily cannulate the brachial artery. These patients were subsequently studied by other techniques and the x-rays were considered adequate but not optimum as compared to the retrograde non-catheter brachial arterial visualization. The Amplatz teflon-needle has proven a versatile, dependable instrument of considerable value and safety to this procedure.

PAROTITIS-HERPANGINA-COXSACKIE VIRUS SYNDROME

The coincident presence of proved Coxsackie virus, herpangina, and parotitis is rare. Four such cases have been reported by Howlett and associates. The infection is seasonal, occurring primarily in the summer months.

Aside from the parotitis the symptoms are similar to those of herpangina and consist of sudden onset of headache, sore throat, dysphagia, abdominal pain, and pyrexia, which continue for two or three days. The local vesicular or ulcerative lesions are usually limited to the tongue, anterior pillars, and soft palate. Involvement of one or both parotid glands occurs simultaneously. The Coxsackie group A virus, considered to be the cause of herpangina, was isolated from the tiny, 0.5-mm. greyish-white papulovesicular lesions of the oral mucous membrane as well as from the saliva of each of the four patients with parotitis. Spontaneous recovery is the rule, the mucous membrane lesions resolving within four to six days. No specific therapy is indicated.

|| Addiction

Cases Treated on a Psychiatric Service

CARL D. KOUTSKY, M.D.*
THEODORE G. LARSON, M.D.**
Minneapolis, Minnesota

REVIEW OF THE problem of addiction in a general hospital psychiatric ward has become important because of the increasing use of new tranquilizing agents and non-barbiturate sedatives. This investigation focused on our experience with patients having the diagnosis of addiction on the Psychiatric Service of the University of Minnesota Hospitals.

Review of the Literature

Statistics regarding the incidence of addiction in the general population are unreliable and difficult to obtain. Rathod¹ emphasized that addictive people do not volunteer their problems and are diagnosed properly only when the physician is alert to the possibility of addiction. Schremly and Solomon² found that even with incentives to look for drug addiction, physicians failed to recognize a large number of drug abusers admitted to a general hospital and pointed out that of the known cases of addiction, only a small number of them were actually reported to official data-collecting agencies.

Blane et al.³ found that improper diagnosis in alcoholic patients is related to two factors: (a) a better social adjustment by the patient leads to missing or at least not diagnosing and treating the patient as an alcoholic, and (b) alcoholic patients with medical or surgical complaints tend to be missed as far as their addiction problem is concerned. They concluded that physicians prefer a medical diagnosis over a social or psychological diagnosis.

Since the introduction of the newer non-barbiturate sedatives and tranquilizers, records consist mainly of case reports and the incidence of their abuse cannot be ascertained. Meprobamate, glutethimide, ethina-

*Associate Professor, Director, Inpatient Service Department of Psychiatry, University of Minnesota.

**Assistant Professor, Staff, Inpatient Service Department of Psychiatry, University of Minnesota.

mate, ethchlorvynol, methypylon, and chlordiazepoxide are several of the drugs known to have addictive properties.^{4,5} Physiological withdrawal symptoms similar to those of barbiturate withdrawal are described for these drugs.^{4,6}

The abuse of these drugs is real and serious beyond doubt, and deaths are known to have occurred following the withdrawal of barbiturates,⁷ meprobamate,⁸ and methypylon.⁹ Gradual withdrawal of the addicting drug is recommended to avoid complications in therapy. Grand-mal convulsions, hyperpyrexia, and delirium are regarded as symptoms of impending disaster.¹⁰ There is no general agreement about specific therapy to control seizures. Blachly¹¹ and Essig⁴ believe that diphenylhydantoin is ineffective in the prevention of seizures due to drug withdrawal, has a small but definable hazard in itself and is, therefore, contraindicated. Pearson and Little,¹² however, recommend using anticonvulsants in withdrawal addicting drugs while Wilhoit¹³ regards the use of diphenylhydantoin as essential in the treatment of alcohol withdrawal.

Method

This study was done in retrospect and thereby avoided influencing the ongoing practice in the hospital. Records were not examined until they were complete and filed in the record room. In order to find all the addiction cases, a double search of all records of patients admitted and discharged from the University of Minnesota Hospitals Psychiatry Service from January 1, 1963, to May 31, 1965, was made. The searches were made by (1) the use of an IBM registry and (2) a review of discharge diagnoses kept on file in the psychiatric office. In addition, a special search was made of all records where the problem of addiction might be related, such as in the cases of acute and chronic brain syndromes.

Findings

Incidence

During the time of the study there were 1,116 admissions to the psychiatric service. Addiction was found in 84 patients (7.5 percent of the total number of admissions). Of

these, 44 patients had a diagnosis of drug addiction and 40 had a diagnosis of alcoholism. Fourteen of those patients who carried a diagnosis of addiction to drugs were known to use alcohol to excess and nine who received a diagnosis of alcoholism were also known to be abusers of drugs. In other words, 27 percent of the patients with addiction diagnoses were using both drugs and alcohol.

Demographic data* on our patients is summarized in Table 1. Forty-six came from communities over 2,500 population and 21 grew up in communities under 2,500 population. In 17 patients, the place of origin was absent from the records.

Forty-one patients (49 percent) were able to pay for all or part of their care in the hospital. According to the Hollingshead Two Factor Index of Social Position,¹⁴ 27 patients were classified in Class I or II. Sixty-four of the patients received previous treatment for addiction, while only 20 were being treated for addiction for the first time. Sixty-eight of the patients admitted to the hospital came on a voluntary basis, nine required a legal hold order, while seven were admitted in an emergency situation because of an overdose of a drug or intoxicant. The patients stayed in the hospital from one day to 286 days with 50 percent staying 30 days or less.

Minnesota Multiphasic

The first valid two-digit code of the Minnesota Multiphasic Personality Inventory is routinely tabulated on the IBM record of all patients admitted to the psychiatric service. All but 14 of our records had valid profiles recorded in the two-digit system. Using the "Physicians' Guide to the Minnesota Multiphasic Inventory" by Good and Brantner¹⁵ as our authority, we recorded the frequency of the two-digit codes in Table 2. Distinct analysis of each code is not the purpose of this paper but one is referred to Good and Brantner for their excellent coverage of this material. Of the valid two-digit codes, 29 cases would be equally associated with a diagnosis of either psychosis or neurosis ac-

cording to Good and Brantner.¹⁵ Briefly, however, we find that scale 2 of the Minnesota Multiphasic Personality Inventory or the scale related to the various depressive syndromes was the highest score in 22 of the patients. Nineteen patients had the highest score on scale 4 which is the scale derived chiefly from patients diagnosed as psychopathic personality, amoral and asocial type. In these patients, lying, stealing, alcohol or drug addiction, and sexual immorality are the most frequent digressions from the moral code. Fifty-two patients, or 74 percent of the total number of valid Minnesota Multiphasic Personality Inventories in our study, had either a high 2 scale or a high 4 scale as a predominant feature.

Suicide Attempt

We found that of the 84 patients, 26 (31 percent) had made previous suicide attempts and that 11 (13 percent) had a diagnosis of psychosis recorded some place in their records.

Drugs Abused

A detailed history of all the drugs the patients had abused was not routinely recorded by our physicians. Most probably, the patient was not able to or was unwilling to identify all of the drugs he had taken. We found the

found multiple abuse of drugs in various combinations.

Disposition

The final disposition of our 84 patients was as follows: nine left against medical advice, two were committed to psychiatric services, two had to be transferred to other wards for medical or surgical reasons, 69 patients received regular discharges and two patients received "other" type discharges. Although continued care was recommended by the physicians on disposition, only twice did they go to the point of commitment. In 13 cases there was no recommendation for follow-up care. For the others continual care was recommended.

Management

Current practice in our hospital includes the use of anti-convulsant therapy in drug withdrawal. Nineteen patients received anti-seizure medications during the time of drug withdrawal (see Table 4).

Anti-Convulsant Drugs

Anti-seizure medication used was either diphenylhydantoin, 16 cases, mephobarbital alone in one case, and a combination of these drugs in two cases. Of the nineteen patients receiving seizure control drugs, none had seizures, while six patients had seizures while being withdrawn without seizure control drugs.

Since phenothiazine drugs are suspected of producing seizures,^{16,17} we recorded the use of these drugs during drug withdrawal (see Table 4). Seven patients on both phenothiazines and anti-seizure drugs had no seizures, while of the nine patients on phenothiazines alone, three had seizures reported during withdrawal. The other three who had seizures were not receiving phenothiazine drugs.

Rate of Withdrawal

Another factor that seems important in the management of drug addiction is the rate of withdrawal from the drug of addiction. In our series, 30 of the patients were withdrawn abruptly while 14 patients were

withdrawn gradually. All six of the patients who had seizures on drug withdrawal were being abruptly withdrawn.

A review of medical management during withdrawal of alcohol produced similar observations. Nineteen of the patients received phenothiazines, while 21 did not. Anti-seizure medication was given to seven patients while 33 did not receive this type of medication. The two patients who had seizures were on phenothiazines and were not receiving anti-seizure medication. All of the alcoholic patients were abruptly withdrawn.

Discussion

The incidence of addiction (7.5 percent) in the patients admitted to our psychiatric unit is a reasonably accurate picture of our experience. A careful search of the records revealed only eight instances of failure to record the diagnosis of addiction on both of the routine record systems kept for each patient. In the patients carrying a diagnosis of addiction, there appeared to be no attempt on the part of the physicians to hide the diagnosis out of empathy for the patients, and the patients were actively treated for addiction with apparent recognition by the physician that addiction was a primary problem for them. However, errors such as failure to recognize addiction problems based on factors related to the physician's personality or to special characteristics of the patient are not accounted for and the rate of 7.5 percent must be regarded as the minimum.

Socioeconomic Status

The patients came from rural and metropolitan areas, and all social and financial classes were represented without any indication that addiction is a special problem either geographically or socially. The seriousness of the illness is most manifest in the chronic nature of addiction with three-fourths of our patients having received previous treatment.

Character Disorders

Factors of depression or character disorder were of major importance in 74 percent

of the patients with valid Minnesota Multiphasic Personality Inventories. Severe personality adjustment problems are suggested by history of suicide attempts in 31 percent of the cases and also by a diagnosis of psychotic disorder on previous admissions in 13 percent of the patients.

Addicting Drugs

The common barbiturates were recorded abused in 33 cases and were the most frequently abused drugs. However, the newer nonbarbiturate sedatives and minor tranquilizers were recorded in 36 cases. This indicates that the newer tranquilizing agents and nonbarbiturate sedatives are of major importance in the problem of drug abuse. When one considers the relatively short time that the tranquilizers have been on the market as compared with the barbiturates, equal caution seems indicated in the use of these particular drugs. Certainly an assumed safety factor of a new drug being non-addicting is one that cannot be considered valid in the treatment of people with chronic neurosis or personality difficulties or with a previous history of addiction.

Codeine preparations, perhaps because they are so readily available in cough mixtures and salicylate pain-killing combinations, are the most commonly abused narcotic preparations. Support of legislation requiring that narcotic cough preparations be sold only on prescription seems indicated.

Non-addicting Antidepressant Drugs

The major phenothiazine tranquilizers and the tri-cyclic and monoaminoxidase inhibitor-type antidepressants do not appear on the list of drugs abused by our patients. This would seem to indicate that these drugs have little appeal to the addictive patient and, therefore, may be a more appropriate choice for the treatment of anxiety and other functional problems encountered in patients with a history of addiction.

Abrupt Withdrawal vs. Gradual Withdrawal

Six of the patients being withdrawn from drugs had grand-mal convulsions during their withdrawal. In surveying the methods

of treatment during withdrawal, these patients have two factors in common: (1) they were all abruptly withdrawn from their drugs, and (2) none of these patients were receiving anti-seizure medications during the time of their seizures. In comparison, 14 patients were gradually withdrawn and, of these, 12 received anti-seizure medication with no seizures recorded. Although this sample of patients is too small to give significant statistical differences, it appears that abrupt withdrawal of the drug of addiction is hazardous, and gradual withdrawal should be routine in the treatment of drug addicts. The use of anti-seizure medication in the management of drug withdrawal is controversial, and since studies thus far have not been conclusive enough to influence clinicians, the use of anticonvulsants in drug withdrawal needs further study. If phenothiazine drugs aggravate seizure proclivity during drug withdrawal, their effect does not appear to be dramatic. Possibly, phenothiazine drugs are safe to use provided anticonvulsant treatment is given concomitantly.

The wide variety of final dispositions on

discharge from the hospital (see Table 1) indicates a serious difficulty in achieving satisfactory follow-up care for the chronic addict. It appears that the medical profession needs to re-evaluate attitudes toward addiction, particularly in regard to post-hospital treatment.

Summary

Addiction to drugs or alcohol was the primary diagnosis in 7.5 percent of the patients admitted to a general hospital psychiatric service. Analysis of these records shows that addiction exists in all social, cultural and financial strata. Addiction in these patients is characterized by its chronic nature and is accompanied by serious personality and emotional disturbances. The abuse of minor tranquilizers and non-barbiturate sedative drugs was found to be of major significance in the problem of addiction. Gradual withdrawal of the drug is recommended to prevent complications in treatment. Controlled studies on the effectiveness of anti-seizure medication during drug withdrawal are needed.

Wringer Injuries

Still
a
Serious
Problem*

JAMES A. GARRICK, M.D.**
Rochester, Minnesota

A NEGLECTED wringer injury can be a horrible sight. The patient may be seen from seven to 30 days after being injured and presents with a necrotic, infected, draining upper extremity. Tendons, nerves, blood vessels, muscles, and bones are exposed. He is toxic, and his hand, functionless.

During the lifetime of the young physician, the wringer injury has been born, has risen to its apogee,[†] and then has been all but forgotten. Orthopedic and surgical residents have been told repeatedly to be careful of prognosticating about wringer injuries and that wringer injuries are bad injuries to treat.

The first electric wringer-washer was marketed in the late 1920s. By 1932 there were more than 200,000 of these appliances in use. This figure steadily rose until the late 1940s when the electric spin-drying washer became popular.

Our ancestors who dried their clothes in the sun by laying them on the grass had no problems with wringer injuries. They washed and rinsed the clothes by beating them on rocks at the riverside, and although hard on fabrics, this method offered little danger to the washer or her observing children. But not everyone had a readily accessible rocky creek bed for washing and a grassy field for drying; so, as washing facilities moved into the basement, clothing was wrung out by hand—an inefficient but innocuous method that caused only an occasional humeral epicondylitis or exacerbated a carpal tunnel syndrome.

Soon washtubs grew a remarkable appendage called the “hand wringer,” which was much more efficient but still not sophisticated enough to be dangerous. When the

*Prize essay at the meeting of the Minnesota Surgical Society, Rochester, Minnesota, May 6, 1966. Also presented as a seminar while Dr. Garrick was on assignment at Gillette State Hospital for Crippled Children, St. Paul, Minnesota, Dr. John H. Moe, chief of staff.

†See Test Your Word Score Page 221.

housewife caught her finger (or her child's) in the hand wringer, she needed only to reverse cranking to limit injuries to subungual hematomas. With the advent of the electrically-powered wringer-washer, the reasonably safe hand-operated wringers were soon doomed to minute car-wash operations and service stations. Now clothing, sheets, fingers, forearms, and various other appendages could be instantly passed between two hard-rubber rollers with the mere turn of a switch.

Even the early appliances were equipped with elaborate safety devices that would automatically release with the presence of an adult hand between the rollers (thereby limiting more than 2/3 of all wringer injuries to children less than 10 years old).¹ However the hand of the two-year-old has approximately the same thickness as a double layer of duofold underwear, and a machine that would release automatically with anything thicker than a linen handkerchief would hardly be practical.

And so developed the "innocent-looking" wringer injury. Since MacCollum's² descrip-

tion (and naming of the injury in 1938), there have been more than 50 papers published dealing with this subject, many of which have obviously been ignored. If such were not the case, the neglected wringer injury would be nonexistent.

Pathologic Features (Figure)

The mechanism of injury is obvious. Who hasn't watched a child observe with rapt attentiveness the disappearance of pieces of clothing between the rollers of a wringer. The temptation to "touch" or "help the clothes go through" is often too great in spite of mother's repeated warnings. Once pulled into the wringer, the panicky child does not have the presence of mind to strike the release lever even if he were able to reach it. So the excursion of his extremity through the wringer stops only as a bony block is reached (that is, the abducted thumb, the elbow, or the axilla)³ and the soft tissue is ground away until help appears.

Unfortunately, the problems often are compounded at this time. Most mothers, con-

Schematic diagram of pathologic sequence in wringer injuries.

fronted by a screaming child with portions of his upper extremity protruding from either side of a wringer do not do the most logical thing by simply releasing the safety catch. They either jerk the arm out against the pull of the moving rollers, stop the rollers and then extract the extremity against stationary rollers, or they may simply reverse the rollers and "wring the arm out" as it were, so the child suffers a crushing injury going in and a tearing injury coming out.² It is indeed fortunate that the sight of a child with his arm in a wringer is such a horrifying one that most mothers immediately rush the child to a physician.

Avulsion of Soft Tissues

The primary injury involved is an avulsion of skin from its subcutaneous attachments. The subcutaneous fat is torn from its superficial and deep attachments, giving rise to crepitation on palpation. As a result of temporary ischemia caused by the wringer itself, edema of all tissues is the hallmark of the first 24 hours. Edema is also increased by venous stasis secondary to the rupture of thin-walled venules.

Minimal-to-moderate bleeding into the soft tissues also occurs early but is usually the result of seepage from multiple ruptures of small vessels and not from a loss of continuity of major vessels. The edema and venous congestion cause increasing tension on the tissues, particularly the skin, which, if unchecked, is lifted from its attachments and thereby from its blood supply. This phenomenon gives rise to the sensation of "floating fluctuance" encountered on palpation.⁴

Vascular Injury

Still greater increases in subcutaneous edema and bleeding not only continue to embarrass venous circulation but also cause arterial irritation and ultimately arterial spasm, thus yielding a Volkmann-like condition.

The generalized venous stasis leads to an equally generalized inflammatory response of all involved tissues, which usually begins within the second 24 hours. At one week,

the inflammatory response is replaced by proliferation of connective tissue which leads to the contractures that are so often seen.

With the typical wringer injury (that is, one without open flaps, deep or extensive lacerations, or fractures) the subcutaneous tissues suffer most, because it is within this plane that the tissues separate. Lacerations are relatively rare (seen in only 10% of the injuries). Free-flap avulsions are more common.

Skin necrosis is usually most extensive over areas likely to accumulate collections of subcutaneous fluid, such as the palm of the hand and the antecubital fossa, or skin surfaces overlying bony prominences such as the styloid processes and the humeral condyles where there is no subcutaneous cushion to absorb the crushing force of the rollers.

Bone Injury

Fractures are rare, occurring in only 2 to 4% of the cases.¹ When present, fractures usually are nondisplaced and often are of the greenstick variety. Unless the fracture site is open by virtue of an overlying flap avulsion, fractures do not offer much of a problem in management.

Soft Tissue Injury

Damage to tendons, nerves, or major blood vessels is a rarity in the typical wringer injury.⁵ When these structures are injured, it is generally a result of unrelieved pressure from the accumulation of subcutaneous and deeper fluids.

Typical damage to muscle consists of micro-hemorrhages. Rarely are muscles per se torn. Not infrequently the muscle, complete with its fibrous envelope, is torn loose from adjacent tissues although it may remain attached at its origin and insertion.⁶ On rare occasions, intramuscular hemorrhage will be extensive enough to merit incision and drainage.

The problems resulting from this type of injury are legion in spite of the small number of tissues that initially are appreciably damaged. Minimally damaged tissues heal

very slowly if the damage is caused by a crushing force. The arterial supply to these tissues usually is adequate at first, but the venous return is grossly inadequate. Also because of the poor circulation, the local tissue resistance to infection is poor.

If the injured site is contaminated, as in the case of lacerations or abrasions, the contaminants usually are easily controlled with standard antibiotic therapy. However, the necrotic or improperly treated wound that has been allowed to become infected often results in a functionless extremity and even in amputation.

Diagnosis

Although the victim invariably is seen early by a physician, treatment in many of these injuries is inadequate. In the neglected wringer injury the typical history is one of the child being seen early in the physician's office or in an emergency room, with very little damage being noted on physical examination (usually there is not much more to see than a slight swelling and abrasions during the first few hours). The inevitable roentgenograms are taken and show nothing abnormal. The child is then sent home and advised to rest his arm.

Since the final outcome of these injuries is all but impossible to predict, a prognostication should never be attempted. However, the physician should have some idea of the probable extent of damage in order to institute the proper treatment. Therefore, it is important to know how the child was extracted from the rollers, how long he was caught in the wringer, how tightly the rollers were set, how much time had elapsed since the injury, as well as the age and size of the child. Surprisingly enough, young children generally have less severe injuries than do older ones, because of the greater elasticity of their tissues and the smaller size of the extremity.

Initial inspection is of value. The presence of blotchy, ecchymotic skin shortly after the accident is an ominous sign, as it signifies potential areas of necrosis. Determining the function of the extremity is of little value, because generally the child is unwilling to

cooperate. It is well accepted that, in injuries of a crushing type, loss of function need not parallel damage (or potential damage) to the extremity.

Although fractures are rare in wringer injuries, initial roentgenograms should always be taken. Because of the extensive damage to soft tissue adjacent to tendons, which often leads to fibrosis and dysfunction of these tendons, fractures when present are slow to heal.

Treatment

The basic premise in the treatment of wringer injuries is to achieve primary healing by means of massive compressive dressings.

First Aid

Immediate first aid should consist of application of a voluminous pressure dressing that is evenly applied, as well as splinting and elevation of the extremity. No attempt should be made to determine the full extent of the injury; the time required to evaluate the injury should be used to transport the patient to a physician.

Antiseptic Procedures

The entire involved extremity should first be gently washed with a hexachlorophene soap and soft-gauze fluffs (never a brush). Whether or not the wound is open, the washing should be carried out under sterile conditions with the operator gowned, masked, and gloved. A second 5-minute scrub with sterile water, sterilized soap, and a change of gown and gloves for the operator should follow. Since the initially unbroken skin may break down soon after the accident, future contamination may thus be prevented.

Surgical Procedures

After the wound is cleansed, any laceration should be thoroughly irrigated and closed primarily.⁷ Only obviously nonviable tissues should be debrided. Jagged edges should be dovetailed but not trimmed for cosmesis. This initial treatment is aimed at closing the wounds and not at restoring full

function. Attempts at plastic-type closures involving rotating skin flaps, Z-plasty, and so forth are ill-advised because excessive handling might compromise the already precarious blood supply to the ischemic tissues.

Suturing should be carried out as soon as the tissues have been cleansed and debrided. Any swelling causes retraction of excessive skin and subsequent difficulty in closure without undue tension. Flaps that have been doubled back to allow access to deeper tissues develop edema rapidly because of the kinking of already damaged veins.

Grafting

Opinions are many and varied regarding the handling of large avulsion flaps. Some physicians recommend suturing the entire flap in place regardless of questionable viability and utilizing the flap as a large pedicle, stating that much of the skin will live in spite of considerable infection.⁸ This technique invariably involves secondary grafting procedures after the infection that usually develops is controlled. To expect a pedicle graft of ischemic, crushed skin (even though well cleansed and defatted) to survive in an edematous, congested, recipient site requires faith of rather heroic proportions.

A second group suggests debriding all tissues of questionable viability, closing what skin remains, and covering the remaining open areas with split-thickness grafts at the initial treatment. Many of the advocates of this method clean and defat open flaps (and even circumferential ones) and use them as the grafting material. Opponents of this practice contend that (1) much of the debrided skin is damaged too much to function ideally as a graft; (2) the procedure takes too long; (3) attempts at placing grafts on a surface that has not become "naturally" hemostatic is asking for the graft to be floated off by pooling blood; and (4) fresh normal skin is readily available with an electric dermatome, a procedure best done seven days after the injury. Hence these critics advocate closing as much viable skin as possible, covering the remaining open areas with an appropriate dressing, and carrying out split-thickness grafting procedures five to seven days later.

Nearly every physician agrees that the use of a primary pedicle-type graft is ill-advised because of the operator's inability to distinguish viable from nonviable tissue and, therefore, because of increasing the possibility of suturing the pedicles to already

Summary of Do's and Don'ts in Treatment of Wringer Injuries

	Do	Don't
Cleansing	Use sterile technique (mask, gown, gloves) Be gentle	Use a brush
Closure	Debride only the obviously nonviable tissue Dovetail jagged edges Work rapidly Grafting procedures in 5 to 7 days Immobilize unstable fractures Reapproximate trimmed nerves	Trim for cosmesis Undertake split-thickness graft immediately Attempt pedicle flaps Primarily repair tendons Use a tourniquet
Dressing	Dress with nonadherent dressings, longitudinally placed 4- by 8-inch gauze sponges, evenly applied gauze fluffs, circumferentially applied cellulose bandage (Curlex), or nonrubber elastic bandage	Use "mechanic's waste" Use rubber elastic bandages
Immediate after-care	Elevate the extremity Administer tetanus toxoid or hyperimmune globulin	Use heat
Later care	Aspirate when there is any sign of subcutaneous pressure buildup Incise and drain if aspiration does not immediately relieve pressure	

doomed skin. The practice of placing a hand, denuded of skin, under an abdominal flap is also generally condemned, because retaining a functional position for the hand under these circumstances is all but impossible.

Tourniquet Not Indicated

Regarding skin viability and grafts, there is one point of almost universal agreement: that the use of tourniquet during cleansing, debridement, or at any time during the early treatment of wringer injuries is one of the surest possible ways to increase the already present ischemia.

Dressings

Superficial "brush-burn" abrasions should be cleansed and covered with an appropriate dressing. Some physicians recommend the use of tulle gras, which is paraffined, coarse-meshed gauze, impregnated with petrolatum, 1% tincture of benzoin, and 1% balsam of Peru. Others use gauze impregnated with a combination of scarlet red and petrolatum. Still others use a sterile fine-meshed gauze soaked in saline or a nonadhering commercially available dressing such as Adaptic.

Nerves, if divided, should be minimally trimmed and reapproximated to decrease scarring by being sutured through the perineurium. Definitive repair may be carried out at a later date if necessary.

Care of Injured Tendons

Tendons should be excised only if they are shredded beyond repair. Primary tendon repair is generally held in disfavor as it appreciably lengthens the operation and causes an increased extravasation of blood and fluid while the severed ends are being hunted and mobilized. Such repair also increases the likelihood of skin-flap necrosis if additional incisions are required to find and mobilize the proximal tendon fragments. Even if attempted, primary tendon repair is often doomed to failure because tendons, which are normally slow healing, heal even more slowly after a crushing injury.

Management of Fractures

Unstable fractures, which are rare, require immobilization if for no other reason

than to prevent further damage to soft tissue. When fractures are unstable, they are generally open as well; but in spite of this, internal fixation, although not ideal, is the treatment of choice. Often this can be accomplished by the use of wire sutures or Kirschner wires for small bones of the hand, the ends being placed subcutaneously and not brought out through the skin. Under no circumstances should plaster casts be used during the initial phases of treatment of wringer injuries.

Compression Dressings

After wound closure all sutured and abraded areas are covered with small overlapping strips of the dressing material. Next four-by-eight inch gauze sponges are applied longitudinally, followed by evenly applied gauze fluffs. The use of "mechanic's waste" is becoming unpopular because of the difficulty of applying this material evenly enough to achieve uniform compression.⁹ A cellulose-type gauze (Curlex) is next applied circumferentially, and this in turn is covered by a nonrubber elastic bandage. The use of rubberized elastic bandages can lead to excessive compression. Care must be taken to eliminate dead spaces, such as those that occur in the palm and result from lateral compression and cupping of the hand. Excessive compression may be alleviated by the placing of a mass of steel wool in the palm in the gauze-fluff layer of the dressing or by the suturing of the dressing through the hand. The sutures are brought out on the dorsum and are tied over a piece of felt or padded button. The affected extremity should then be elevated and the circulation of the finger tips checked almost constantly.

Cooling of Tissue

The use of heat to the involved extremity is also to be condemned; however, cooling of the extremity decreases the metabolic rate of the damaged tissues and may well be the determinant factor in the survival of the skin and deeper tissues. One of the new, smaller cooling blankets can be incorporated into the dressing, just superficial to the layer of gauze fluff; this serves not only as an ad-

ditional splinting material but also as a means of decreasing the temperature of the extremity.

Even if no open wounds are present at the initial treatment, the patient should be given tetanus prophylaxis. The newer hyperimmune human antisera negate most of the problems seen previously with horse serum.

The time lapsing before the first change of dressing and the examination of the extremity varies. Some physicians recommend that the extremity should be inspected every 12 hours until the exact status of the wound can be ascertained. Others report equally good results by changing the initial dressing two to three days after the injury and then seeing the victim on an outpatient basis. The victim is admitted to the hospital only in the event of gross tissue necrosis or mass swelling in spite of compression dressings.

Incision and Drainage

However, all agree that if there is any evidence of a subcutaneous pressure buildup when the first dressing is changed, aspiration should be immediately attempted; and if this does not alleviate the pressure, then

incision and drainage must be carried out.

When incision and drainage are necessary, longitudinal incision is made to the level of the fascia, as the majority of the fluid collections are external to the fascial layers. If the underlying muscles still seem under undue tension, the fascia enveloping the muscles must also be incised. After drainage, the fascial layers are not closed, but the skin is loosely approximated without tension and the compression dressing reapplied. With this method, there is no necessity for repeating the incision and drainage procedure in the same area.

Summary

Proper early care of a wringer injury requires little more than strict adherence to accepted surgical principles which include cleansing and debridement, primary skin coverage, the use of compression dressings, adequate immobilization, and careful observation.

Wringer injuries will ultimately follow the wringer-washer into history and "neglected wringer injuries" should precede this appliance into antiquity.

The Doctrine of Signatures

According to this doctrine nature has placed upon natural objects in general (animals, plants and minerals) a sign, or marking, or has given them a symbolic appearance, to indicate their special usefulness for the treatment of certain maladies or for the diseases of certain organs. Some of the keenest minds of the past centuries accepted this doctrine with no apparent difficulty.

Like cures like, that is the principle underlying the doctrine. Therefore a plant with a leaf shaped like a kidney, would be good for kidney trouble, hence the kidney wort. We have also the liverwort, because its leaf is seemingly shaped like the liver. Frequently the supposed signature (i.e., the resemblance) was far-fetched indeed, as for example, in the case of the tough gelatinous fungus, known for centuries as the Jew's ear which was used as a cure for ear complaints.

Erysipelas, because it is accompanied by a bright-red, feverish rash, was treated with red things — red pepper, cranberries, and red flannel. In small-pox red bed-coverings were used to bring the rash to the surface. When Edward II (1284-1327) King of England had small pox his physician, John of Gaddesden, directed that everything about the room, the dresses of the patient and attendants, the bedding and furnishings should be scarlet. Four hundred fifty years later, when Francis I (1708-1765) emperor of Germany had small pox, he was treated in a similar manner.

Avicenna (890-1037 A.D.) the renowned Arabian physician was convinced that because the blood is red, substances which are red in color must be used in treating diseases of the blood. Nine hundred years after Avicenna doctors were ordering red wines for patients poor in blood, and white wines for those whose "blood was too rich."

We know now that the Doctrine of Signatures is just the veriest nonsense. Whatever benefits were derived by such beliefs resulted merely from the power of suggestion.*

On the Art of Medicine

Medicine is both a science and an art. . . . It is an art when it becomes necessary to apply it to a human being who is ill, and this is especially true when the manner of treatment is under consideration. It is in this art that the physician reveals how much talent he possesses; he reveals himself as a true artist by the particular form of remedial preparation which he decides to administer to his patient, by the felicitous choice which he makes between remedies, and by the favorable manner in which he combines them. — Armand Trousseau (1801-1867)

Heart Symposium

Symposium on Emotions and Heart Psychophysiology of the Coronary Heart Disease Patient sponsored by L. E. Phillips Psychobiological Research Division of North Memorial and Mount Sinai Hospitals in conjunction with the Minnesota Heart Association, Sunday, April 2, 1:30 p.m., North Memorial Hospital Auditorium, Minneapolis, Minnesota.

Massive Upper Gastrointestinal Bleeding

Caused
by
Aortojejunal
Fistulization

RICHARD E. LARSON, M.D.
LOUIS C. LICK, M.D.
S. R. MAXEINER, JR., M.D.
Minneapolis, Minnesota

AORTOENTERIC FISTULIZATION producing massive gastrointestinal bleeding has been reported with increasing frequency as a delayed complication of abdominal aortic aneurysm resection and grafting.

Including three previous cases known to the authors, 84 cases collected from the literature^{1,3,4,5,6,7,8,9,10,11,12} and the case to be described, a total of 88 patients were found to suffer from this lesion.

The occurrence rate of aortoenteric fistulas following abdominal aortic surgery is between 0.3 and 5 per cent.^{7,5} In 80 per cent of cases fistulization is into the distal duodenum or into the proximal jejunum in the remainder.

The average time for development of a fistula is 24 months for homografts and six months for synthetic prostheses. The explanation for this discrepancy probably lies in the tendency for gradual disintegration of the central portion of the homograft, the area where most homograft fistulas occur (80%). In theory, no such degeneration develops in teflon and dacron prostheses. Therefore, when fistulization does develop with this type of prosthesis it is most likely related to technical problems at the proximal suture line and will occur early. The grafts employed in the collected group of 88 patients are listed in Table 1. Homografts predominate and will probably continue to be the source of fistulization in a significant number of patients in the future.

Diagnosis

Gastrointestinal Bleeding

The diagnosis of aortoenteric fistula⁵ rests mainly on obtaining a history of previous abdominal aortic surgery in a patient with gastrointestinal bleeding. A pulsatile abdominal mass is confirmatory evidence in a minority of patients. It is our opinion that in the actively bleeding patient laparotomy should be performed as soon as feasible and

the presumptive diagnosis substantiated or refuted by exposing the previous operative area.

Massive Melena

Gastrointestinal hemorrhage was present in all patients studied and in almost all hypotension and massive melena were noted. The time between onset of hemorrhage and death or surgical intervention varied from two hours to eleven months. However, experience has shown that only a relatively small portion of these patients will die as a result of the initial hemorrhage and that there exists sufficient time for surgical correction if this complication is suspected.

Causes of Failure

Technical Errors

Several technical faults which may cause aortoenteric fistulae include: faulty proximal suture line, discrepancy between the size of the host aorta and the selected graft, poor quality of proximal aortic cuff, failure to interpose viable tissue (peritoneum, omentum or aneurysm wall) between the aortic graft and the intestines, and injury to the proximal small intestine at the time of aortic mobilization. In addition, damage to the vasa vasorum* may impair healing at the proximal suture line.¹⁰

Surgical techniques must avoid these errors to prevent fistulization. Dissection of abdominal aneurysms in an intraluminal plane will preserve the outer media and adventitia, allowing this retained arterial wall to serve as an excellent anterior reinforcing

layer for the prosthesis and proximal suture line.

Local Infection

Local sepsis developing in a retroperitoneal hematoma due to faulty hemostasis will almost surely result in dehiscence of the proximal suture line. That a large retroperitoneal hematoma may itself dissect through the layers of the gut is theoretically possible. The close anatomic proximity of the distal duodenum and first portion of jejunum obligates fistulization from the aorta into this portion of the intestinal tract.

Precautions

Massive antibiotics and an osmotic diuretic should be administered intravenously as soon as the need for aortic re-resection is recognized. Resection of the entire previously placed graft appears mandatory, in spite of any technical difficulties. If necessary, a pedicle graft of omentum may be placed anterior to the new graft and interposed between it and the intestines. The problem posed when an infected proximal suture line is encountered as the basis for fistulization is almost insurmountable. It has been suggested⁶ that a portion of adherent gut along with the involved segment of aorta be resected en block to prevent reinfection of the operative area. This plan presents certain technical difficulties but should be feasible in some cases.

Results

A summary of results obtained in the 88 patients is presented in Table 2. Twenty-six patients were not operated upon; all of these succumbed to massive hemorrhage. Eight patients were subjected to non-definitive surgical procedures such as abdominal

exploration, "blind" gastric resection or local patching of the aortic fistula; and all of these patients expired in the early postoperative period. In contrast, nineteen of fifty-four patients treated by resection and grafting survived. This represents only a 35% survival rate, admittedly less than ideal, but is in keeping with the severity of the disease. We believe that if earlier diagnosis is followed by aggressive surgical treatment, more of these patients will be salvaged.

Case Report

History

A 67-year-old white man was seen on the morning of August 28, 1965, complaining of recurring melena during the preceding twenty-four hours and of a syncopal episode immediately prior to admission. There was no significant past history of gastrointestinal complaints, abdominal pain or ingestion of drugs or alcohol. He denied intermittent claudication. In 1957 he had undergone emergency resection and grafting for a ruptured abdominal aortic aneurysm. The aorta was replaced with a nylon bifurcation prosthesis and the patient made an uneventful recovery.

Findings

Physical examination revealed a pale, anxious man who was in no pain. His heart rate was 104 and his blood pressure 70/40. The lungs were clear and there were no cardiac murmurs. There was a healed midline scar and a prominent, pulsatile mass in the mid-abdomen. A systolic bruit was heard best immediately to the left of the umbilicus. The right femoral pulse was diminished and the right popliteal and pedal pulses were absent. Rectal examination disclosed mahogany colored stool. Bright red blood was recovered from the nasogastric tube.

His hemoglobin was 11.2 gm. % and hematocrit 39. The blood urea was 29 mg. %. Other laboratory studies, including an ECG., were within normal limits.

A diagnosis of aortoenteric fistula was made and the patient prepared for surgery. He received par-enteral fluids, one unit of plasma and two units of whole blood. A Foley catheter was inserted and a central venous pressure monitor established.

Surgical Procedure

The abdomen was entered and no evidence of disease was encountered during a rapid examination of the upper gastrointestinal tract. The transverse mesocolon was elevated and dissection was begun in the region of the root of the mesentery. Several loops of proximal jejunum were tightly adherent to the area of previous aortic resection (Figure 1). After achieving preliminary proximal control by passing a tape around the aorta at the level of the aortic hiatus the coils of jejunum were carefully dissected off the aortic prosthesis. The fistula was encountered 4 cm. distal to the left renal vein. Aortic bleeding was controlled with digital pressure while further dissection allowed placement of

a proximal aortic clamp. The jejunal defect was temporarily controlled with a non-crushing clamp and later meticulously closed (Figure 2). The nylon prosthesis was densely adherent to surrounding structures, and for this reason it was elected to oversee its proximal end and leave it in place. A 16 mm. Dacron bifurcation prosthesis was then sutured to the short aortic cuff below the renal arteries and anastomosed distally as indicated in Figure 3.

Progress

His postoperative course was uneventful until the 10th day when he developed a mechanical small bowel obstruction necessitating reoperation and division of numerous adhesions. His recovery was further delayed by a prolonged period of ileus and the development of jaundice. Both gradually subsided and the patient was dismissed on the 36th postoperative day.

Disintegration of Original Nylon Prosthesis

On October 30, 1965, he was re-hospitalized com-

Fig. 1.— Findings at surgery. Note adherent loops of proximal jejunum in region of previous aortic surgery.

Fig. 2.—Proximal and distal aortic control and closure of jejunal defect.

Fig. 3.—Completed anastomoses. Nylon prosthesis oversewn and left in place.

plaining of severe upper abdominal and left flank pain which had become progressively worse over the previous three days. Physical examination revealed a pale, rather cachectic man with a temperature of 100.6 F., pulse of 100 and blood pressure of 140/90. There was a 10 × 8 cm. mass in the left mid-abdomen, which was pulsatile along its medial border. No bruits were heard and the peripheral pulses were intact. Roentgenograms of the abdomen were not helpful. The white count was 15,600 with 89% PMNs. The hemoglobin was 10.0 gm. %.

A diagnosis of false aneurysm, probably arising from the proximal suture line was made, and while preparations for surgery were being completed he developed massive hematemesis and become hypotensive.

Second Operation

At surgery proximal aortic control was again obtained prior to retroperitoneal dissection. A large hematoma was encountered anterior to the dacron prosthesis which was entirely intact. There was a large defect in the proximal jejunum adjacent to the hematoma. After evacuation of the hematoma there was apparent free back bleeding from the area of the left common iliac artery where the previously placed left limb of the nylon prosthesis had been sutured in 1957 (Figure 4). Here the nylon prosthesis had virtually disintegrated, leaving a wide open defect. This area was oversewn and the nylon prosthesis was removed completely.

The patient then made steady improvement until the 7th of November when he suddenly developed signs of pulmonary infarction in the left lower lobe. He was reluctantly started on anticoagulants. On the 9th of November a mass in the mid-abdomen was noted, along with gastrointestinal bleeding and hypotension. Although the situation seemed hopeless, re-exploration was carried out and again a large posterior hematoma was encountered. The source of the bleeding could not be determined. A large defect in the proximal jejunum was again present. Closure of the bowel wall was extremely difficult because of its friability.

Following this procedure there was brief improvement, but further intestinal hemorrhage ensued and the patient expired on November 26, 1965. Unfortunately a postmortem examination was not allowed by the family.

Fig. 4.—Nylon bifurcation prosthesis removed at surgery (see text). Arrow indicates site of prosthetic disintegration.

Comment

Although progressive disintegration of ivalon, nylon, orlon, amylon and polyethylene prostheses is well known,³ the particular complication of back bleeding from one of these prostheses left in situ has not been described heretofore. It is painfully clear that the further disruption of the previously placed nylon prosthesis (1957) which was not totally resected and resultant hemorrhage caused the patient's demise.

We would therefore strongly recommend that in any case of fistulization from a deteriorating aortic prosthesis it be removed from any vascular continuity regardless of technical difficulties involved.

Conclusions

From continuing disintegration of the residual nylon prosthesis this experience has convinced us that any previously placed prosthesis, be it homograft or plastic, should be removed completely at the time of corrective surgery.

Early diagnosis of aortoenteric fistulization is the key to proper therapy. It depends upon constant awareness of the possibility of this lesion developing in any patient who has had previous abdominal aortic surgery. It should be emphasized further that there is usually sufficient time to allow these patients to undergo abdominal exploration and corrective surgery.

"Endicott's Prescription for Painful Labor"

Zerobabel Endicott was the son of Governor Endicott of Massachusetts and a practicing physician in the seventeenth century in the city of Salem.

For difficult labor, he recommended that a lock of hair from a virgin half the age of the woman in labor was to be cut into small powder and dried with twelve ant eggs in the bread oven after the bread has been removed. This powder was then to be given with a quarter of a pint of milk from a red cow, or in the absence of milk strong ale could be used.

Have Faith

Faith is dead to doubt, dumb to discouragement, blind to impossibility — Defender

Platitudes are among the most useful things in the world for those who know how to use them, for truth is not the worse for being obvious, undeniable, or familiar.

President's Letter Continued from page 167.

It is our obligation to foster the patient-physician relationship as much as possible and to actively discourage the patient-agency relationship whenever we can. As physicians we have already too long ignored and neglected our professional role in this area and

should not further abrogate our responsibilities.

Junket

I shall never forget my first meal in that hospital (St. Germicide). There was quite a good deal of talk about it beforehand. My nurse kept telling me that on the next day the doctor had promised I might have something to eat. I could hardly wait. I had visions of a tenderloin steak smothered in fried onions, and some French-fried potatoes, and a tall table-limit stack of wheat cakes, and a few other incidental comfits and kickshaws. I could hardly wait for that meal.

The next day came and she brought it to me, and I partook thereof. It was the white of an egg. For dessert I licked a stamp; but this I did clandestinely and by stealth, without saying anything about it to her. I was not supposed to have any sweets.

On the occasion of the next feast the diet was varied. I had a sip of one of those fermented milk products. You probably know the sort of thing I mean. Even before you've swallowed it, it tastes as though it had already disagreed with you. The nurse said this food was predigested but did not tell me by whom. Nor did I ask her. I started to, but thought better of it. Sometimes one is all the happier for not knowing too much.

A little later on, seeing that I had not suffered an attack of indigestion from this debauch, they gave me junket . . . I know not how it may be in the world at large, but in a hospital, junket is a custard that by some subtle process has been denuded of those ingredients which make a custard fascinating and exciting. It tastes as though the eggs, which form its underlying base, had been laid in a fit of pique by a hen that was severely upset at the time.

Hereafter when the junket is passed round somebody else may have my share. I'll stick to the mince pie a la mode.

Many overweight patients can benefit from the appetite control provided by the sustained anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action of amphetamine; tranquilizing action of meprobamate; prolonged action through sustained release of active ingredients.

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.) SUSTAINED RELEASE CAPSULES
WITH MEPROBAMATE (300 mg.)

**to help establish
a new dietary pattern**

Contraindications: Dextro-amphetamine sulfate: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Psychiatry and Allergy

THAT THERE IS some relationship between the psyche and most allergic illness has long been recognized. However, the extent of the role of psychologic forces in their manifestations has been the subject of much debate. In regard to bronchial asthma, this relationship was given particular impetus by French and Alexander in 1941 when they proposed the hypothesis that wheezing is a form of crying and is the result of anxiety over separation from or rejection by the mother. The proof of such a hypothesis would be difficult, and presently this hypothesis is not a proven fact though it is accepted by many in the medical profession. Much work has been done attempting to prove French and Alexander's hypothesis and to describe the "typical personality" of the allergic or asthmatic individual. Groups of patients presenting at allergy or psychiatry clinics or institutionalized for various reasons have been tested with various subjective and objective personality tests. Impressions and conclusions from direct interviews have been used, and the presence of allergy has been confirmed on a few occasions by history, examination, and skin testing. The studies have often found the individual to be restricted, hostile, and rebellious towards figures of authority. Psychoanalytically the allergic patient has been described as fixated at the oral-anal level of personality development.

The patients have been said to view themselves as cynical, irritable, and grouchy. In the September issue of MINNESOTA MEDICINE Rusten and Rusten* undertook what must have been an exhausting review of the records at the Red Wing Training School. They conclude that more of the atopics committed crimes against persons and property than did nonatopics. This supports several other investigators, notably Berendregt, who feel that allergic individuals (particularly asthmatics) tend to be hostile.

As one reviews much of the work that has been done in the area of the psychological aspects of allergic disease several observations are noteworthy. First and foremost, many of the studies have not reported adequate criteria for classifying a patient as allergic or non-allergic. Often this was determined by history as given by the patient only, and there was no confirmation. Also, the types of allergy included in the "allergic" classification were only rarely mentioned. In several studies the population from which the groups were derived was heavily biased: for example, allergic patients referred to a psychiatric clinic. Few studies have been made comparing the personality characteristics of the so-called allergic group with those of another group suffering from chronic illness of comparable severity, and finally many of the studies were poorly controlled, if controlled at all. Few of the

brand of sustained release capsules

ALL-DAY OR ALL-NIGHT RELIEF

Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate), 50 mg. of phenylpropanolamine hydrochloride, and 2.5 mg. of isopropamide, as the iodide.

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*. **Contraindications:** Patients with glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder neck obstruction. **Precautions:** Use with caution in the presence of hypertension, hyperthyroidism, or coronary artery disease; and, in patients who may operate vehicles or machinery, warn of possible drowsiness. **Note:** Since the iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake, it is suggested that 'Ornade' be discontinued one week before these tests. **Side effects:** Drowsiness; excessive dryness of nose, throat, or mouth; nervousness; or insomnia may occur rarely, but are usually mild and transitory. Other known possible side effects of the individual ingredients are: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, and difficulty in urination.

Smith Kline & French Laboratories 

writers venture an opinion as to whether the psychological changes seen are the cause or the result of the illness. This is why it would be helpful to have a study comparing the findings in allergy with those in another chronic illness. Most allergists feel that one would be hard-pressed to describe a typical allergic personality; several well-constructed studies have indicated that there probably is not a typical personality either in the affected individual or in his mother.

In a comprehensive article that appeared in 1964, Freeman et al.¹ reviewed the majority of the related work that has appeared since 1950. They emphasize the findings that have been supported and point out the need for well-controlled experiments designed to uncover the relationships between psychology and allergy. Of most pertinence to the clinician is the fact that three of four recent studies have demonstrated psychological differences between groups varying in the extent of definite allergy as confirmed by skin and other provocative diag-

nostic procedures. There was an inverse relationship between the amount of true allergy present and the severity of the psychological disturbance. These findings would explain many of the discrepancies found among previous studies, because many of the groups of supposed allergic patients were in fact heterogeneous samples composed of those with and without significant immunologic sensitivity.

Freeman points out that though recent studies with the more carefully constructed groups are promising, confirmatory and more extensive studies are needed. However, in light of what has been done it behooves the clinician who may see patients with such illnesses as asthma, rhinitis, urticaria or eczema to carefully consider the role of true atopy in the production of a given individual's respiratory or dermatologic symptoms before saying the complaints are due to his "nerves".

Conservative Use of Thyroid Hormone*

I APPLAUD Dr. Olin's plea for conservatism in prescribing thyroid hormone. It sometimes seems to many endocrinologists that most patients who need thyroid hormone do not receive it and most who receive it do not need it. While this may not really be so, physicians are urged to exercise good clinical judgment in the administration of thyroid. If given in small or moderate dosage, these hormones may be harmless as placebo therapy, but it is neither "good medicine" nor intellectually satisfying to the physician for him to give thyroid indiscriminately.

When it has been decided that a given patient should be treated with thyroid substance, the physician should remember the effect the various thyroid hormone preparations have on thyroid function tests. He should remember that many patients who are

euthyroid while on treatment with l-thyroxine will have a higher-than-normal protein-bound iodine (PBI) value, all patients who are euthyroid on treatment with l-triiodothyronine will have a lower-than-normal PBI, and many patients who are euthyroid on treatment with desiccated thyroid or thyroglobulin will have a lower-than-normal PBI if the preparation used contains a significant amount of l-triiodothyronine; the thyroidal uptake of radioiodine (¹³¹I) by most of the patients treated with any of these substances will be markedly suppressed. If these facts are kept in mind, one will not fall into the trap of incorrectly changing the dose of thyroid hormone because of abnormal values of PBI or ¹³¹I uptake produced by the administered hormone itself.

Dr. Olin is rightly skeptical of the syndrome of "metabolic insufficiency." Many

THE S.S. HOPE is a floating medical center — a fully staffed and fully equipped modern hospital which is the vehicle by which Project HOPE fulfills its mission of carrying American medical treatment and training to foreign lands where such help is not only needed but wanted. Project HOPE is a nongovernmental, nonprofit organization which is financed solely by voluntary contributions from individuals and private enterprise of North America.

THEIR HOPE — Although thousands of natives are treated on ship and ashore, the primary objective of HOPE is teaching. Every HOPE physician, nurse, or technician has his local counterpart who is trained to continue modern treatment after the ship leaves. It is a seeding process which multiplies in the underdeveloped country to improve the health of its citizens and thus their productivity and thereby creates a progressive economy and a higher living standard. The kind of economy in which communism cannot thrive!

OUR HOPE — HOPE — an acronym for Health Opportunities for People Everywhere — is a young Project only in its fourth year of operation but already the evidence is incontestable that its missions are highly successful, not only in the interchange of medical knowledge but also in promoting international friendship and goodwill.

YOUR HOPE — HOPE's basic professional staff of nurses, technicians, etc., are paid a nominal salary but most of its teaching physicians and dentists serve without financial compensation. This makes it not only our most successful foreign aid program but also our cheapest. Nevertheless, private contributions are essential. You may participate by drawing and mailing a check to:

Project HOPE

P. O. Box 550

Chicago, Ill. 60690

endocrinologists are not sure that this syndrome actually exists. Certainly it is a very rare condition, and the vast majority of patients in whom this diagnosis has been made have psychoneurosis but no thyroid disorder.

In his article Dr. Olin mentions the use of thyroid hormone for the treatment of the ophthalmopathy of Graves' disease. With the discovery of long-acting thyroid stimulator (LATS), formerly held concepts of the

cause and treatment of this ophthalmopathy are being seriously challenged. Thyroid hormone seems to have little place in such treatment except for the correction of myxedema in those patients who have become hypothyroid as a result of ablation of the thyroid.

I hope physicians in general will adopt Dr. Olin's conservative attitude toward the therapeutic use of thyroid hormone.

Alcoholism and the General Practitioner

WE HAVE on our hands an insidious problem of massively endemic character and epidemic proportions: alcohol addiction. To the three leading causes of death — accident, cardiovascular disease, and cancer — there are three major contributing factors: each representing an addictive problem, namely: alcoholism, obesity, and tobacco.

Alcoholism is no longer a punitive but rather a socio-medical problem. Since 1935 thousands of alcoholics have demonstrated that they are neither helpless nor hopeless; through Alcoholics Anonymous they have arrested their illness. Not all, however, have been so fortunate. We are in error if we expect every alcoholic to be able to free himself from his addiction thru AA without the ancillary or primary support of other disciplines, including the medical profession.

Therefore it is unrealistic and futile for us to merely advise the alcoholic to stop drinking. He would if he could; but he can't. We must repudiate all this cavalier nonsense that the alcoholic lacks motivation, that he must sink to the bottom of the barrel or into the gutter before he can rise again, that he should humble himself on his knees and implore help.

To tell a spouse that the alcoholic husband or wife is not ready to stop drinking is tantamount to telling a patient with early cancer to return the following year when the tumor is larger and more invasive. We must intervene before the development of such figurative metastases as family aliena-

tion, job loss, and irreversible personality deterioration.

Shifting blame or rationalizing motives is a normal defense built on fear, for the alcoholic is afraid of life and knows that admitting his problem will mean surrendering the crutch he has a need to keep and use.

Like all other addictions, alcoholism is an escape mechanism and a comfort-seeking syndrome. As Kahlil Gibran, the Lebanese poet, has expressed it: "Comfort is a stealthy thing that enters the house as a guest, then becomes a host, and then a master." Since the alcoholic is not particular what agent he uses to secure his objective, there is always danger of a transference addiction involving the use of tranquilizers, barbiturates, amphetamines, or other drugs that can be just as destructive as alcohol.

Though becoming an alcoholic may be understandable, remaining one is neither understandable nor defensible with present interdisciplinary help available.

At Willmar the overwhelming proportion of patients who are psychologically evaluated have clear neurotic profiles. Psychoneurosis in its various manifestations, of which addiction is but one, is recognized as a treatable type of emotional illness. Though approximately 20 percent of alcoholics admitted to Willmar State Hospital cannot be rehabilitated because of chronic brain disease or

BE A MYTH- MONGER #1

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

APACHE PLAZA MEDICAL COMPLEX IS TOO EXPENSIVE.

To be completely fair, some doctors think that's *not* a myth. For half the cost they can rent space above a beer joint in a run-down neighborhood. But, for the doctor who buys top-flight equipment, hires first-rate help, and avoids buying used cars because he doesn't want to take on someone else's problems . . . for that doctor, Apache Plaza Medical Complex makes sense. And it isn't expensive. It's just first class.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

BE A MYTH- MONGER #2

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

YOUR PATIENTS WON'T FOLLOW YOU TO A NEW MEDICAL BUILDING NEAR A SHOPPING CENTER.

Funny. That's what people told us when we built Apache Plaza in the first place. "People won't come all the way out here to shop." But they do—some from the other side of Minneapolis. Patients will follow the *good* doctor—wherever he goes.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

character disorders and sociopathy which render them unamenable to group or individual counseling, 60 per cent of the remainder who receive treatment at our Willmar institution can be rehabilitated by concerted multidisciplinary effort.

While the medical profession must comprise the first echelon in the crusade against alcoholism, sociologists, psychologists, pastors, and others dealing with human problems must also recognize and openly acknowledge their joint social and moral responsibility to revitalize the alcoholic by imbuing him with a love of life so com-

prising and irresistible that he will choose full dedication to it rather than escape from it.

Finally, for greater permanence in the control of alcoholism, it is ethically incumbent on the medical profession to assist in changing the social image of alcohol consumption within the United States. By precept and example we physicians must convey the idea that it is an individual's personal prerogative to abstain from alcohol. Just as it is socially acceptable to take a drink, it should be equally acceptable to decline one and yet be considered 'one of the crowd.'

Congenital Hemolytic Anemia

ANALYSIS OF MANY cases of congenital hemolytic anemia has for a long time been a source of frustration to the hematologist. Not only did he find himself hard pressed to help his patient, but he was even denied that ultimate pleasure, the ability to make an exact diagnosis. It was, no doubt, during a period of extreme dyspepsia engendered by the study of such a patient, that the sonorous title, "Congenital Non-Spherocytic Hemolytic Anemia," was invented. Such a tribute to medical ignorance could not long stand alone, so that Selwyn and Dacie, on the basis of a difficult and mysterious "auto-hemolysis test," soon subdivided the group into Types I and II, and the confusion began compounding.

Fortunately, there has been an explosion of both interest and information in the field of red cell biochemistry in recent years; and, with these developments, the congenital hemolytic anemias have begun to yield their secrets. A number of enzyme deficiencies have been found which appear to explain many of these cases, and one would predict that eventually biochemical mechanisms for all such cases will be uncovered. The most common defect is glucose 6-phosphate dehydrogenase deficiency, a sex-linked abnormality which usually has overt manifestations only after exposure to oxidant drugs. That this is not always true is shown by the case

reported in this issue. Deficiency of this enzyme is most common in Negroes, but is also seen in certain Caucasian groups, such as Greeks, Sephardic Jews, and others.

It is important to make a diagnosis of glucose 6-phosphate dehydrogenase deficiency, since many of the problems of these patients are avoidable if they are not exposed to certain drugs or chemicals. Unfortunately, a simple and reliable test that would ferret out all patients in all situations has been hard to find. Heterozygous females, since their enzyme levels may approach normal, are difficult to diagnose. Similarly, patients with high reticulocyte counts may give misleading laboratory results since reticulocytes have high levels of enzyme. This latter problem is particularly vexing since it may make diagnosis impossible immediately after a period of acute hemolysis, which is, of course, just the time when one usually wishes to make a diagnosis. The quantitation of Heinz bodies, as described by Beutler, is difficult and frequently unreliable. A variety of screening tests, based upon the rate of methemoglobin reduction by red cells or the rate of reduction of various dyes by red cell hemolysates, have been described. One rather simple "spot test" is commercially available. Unfortu-

nately, all these tests are more or less cumbersome and at times inadequate. Jacob and Jandl¹ have just reported a test for glucose 6-phosphate dehydrogenase deficiency which they state is valid both in female heterozygotes and after acute hemolysis when reticulocyte levels are high. The test appears simple and within the capabilities of many clinical laboratories. Hopefully it will make detection of red cell glucose 6-phosphate dehydrogenase deficiency levels more widely and reliably obtainable.

Whatever the test employed, however, efforts should be made to make a diagnosis of the exact enzyme deficiency in any case of congenital hemolytic anemia. It is now possible to prevent most clinical problems in the largest group of these cases; and eventually, as understanding of red cell metabolism increases, even specific therapy may become available.

Urine Collection for Microbiologic Study in Females*

SINCE THE cornerstone of diagnosis and treatment of infection of the urinary tract is the identification of significant bacteria in the urine, it is essential to consider the techniques of collection of adequate specimens of urine for microbiologic study. Certainly, infection of the urinary tract is the commonest problem in the field of renal disease.

The procedures used to obtain a representative sample of urine must overcome the hazard of contamination. This is much more difficult in females than in males because of the genital anatomy and the possibility of contamination of the specimen by vaginal flora. Currently, three techniques are available for collection of urine for microbiologic study. These include catheterization, the midstream clean-voided collection, and needle aspiration of the bladder.

Catheterization does not eliminate entirely the problem of contamination since the catheter must pass through the urethra and can carry contaminants with it. Also a small but definite risk exists that the catheter itself may carry infection. Therefore, it is rarely needed in obtaining specimens for culture.

Needle aspiration of the bladder appears

to eliminate the problem of contamination and has not been accompanied by recognized complications in our experience. However, the procedure must be performed by a physician; therefore its use is limited to specific situations where low colony counts may be significant or to female patients from whom an adequate clean voided specimen cannot be obtained.

An adequate specimen can be obtained from most ambulatory females by means of the midstream clean-voided method but, as in any specimens for culture, careful attention must be given to rapid transportation and bacteriologic study using adequate quantitative techniques. Among ambulatory female patients seen at the Mayo Clinic, intermediate bacterial colony counts of less than 100,000 are being found in only approximately 7.5% of the specimens collected by this technique. With a repeat urine culture this percentage of possible contamination can be reduced even further, but we are also aware that colony counts of less than 100,000 can occur primarily in patients who have chronic infection secondary to anatomic abnormalities in the urinary tract, such as nephrolithiasis.

The midstream clean-voided technique becomes virtually worthless when left to personnel who do not understand the pro-

cedure. Close supervision is required, preferably by designated personnel specially trained in the procedure. In most situations the patient cannot be left to collect her own specimen, but must be assisted by a nurse using proper precautions and techniques. When this procedure is followed, adequate specimens can be obtained for appropriate diagnosis and subsequent treatment.

Hospitalized patients present a more difficult problem, since it is often impossible to collect an adequate specimen from a female in bed by either midstream clean-voided or catheterization techniques. When a specimen is required from patients in this situation, we often rely on the bladder aspiration technique.

Addiction*

IT IS HEARTWARMING to see more articles that depict the problems encountered on a psychiatric service in a general hospital setting.

Although specific topics are relevant and pertinent, of more importance is the awakening realization, although belated, that the general community hospital is a focal "melting pot" of psychosocial problems. The reactions to tension, fear, rage, hate, and the need for love are becoming acceptable vectors** of disease. Society is demanding a new assessment — a psychologic "vivo," not

"vitro," study. People must come to accept their basic responsibilities to one another and the part they play in contributing to the "disease" state.

The general hospital setting can become a cohesive force in this direction by applying the total patient care concept rather than following the former system of considering solely the physical status of the individual. The crossroads are being reached; the community hospital is one way of seeking a final common path. Let us assist in its fruition and expansion.

Richard M. Steinhilber, M.D.

The Editor's Soliloquy

I Almost Broke My Arm

In looking over some of the correspondence in my files in order to eliminate some of its bulk, it was gratifying to reread some of the comments of satisfied readers:

"This week I have had a quiet day at home in which I could go through a lot of accumulated material, including copies of MINNESOTA MEDICINE — which has steadily improved under your editorship until it is now genuinely outstanding.

"Please extend my congratulations and appreciation to whoever did the condensing of my paper. He had it down to half its original length without sacrificing any important detail, thereby improving its readability and overall effectiveness."

Walter H. Judd, M.D.

"Thanks again for sending the copy to Dr. Roland Schoen, *Editor of ARIZONA MEDICAL JOURNAL*. I appreciate very much your helping my good friend."

Haddon Carryer, M.D.

Mayo Clinic

"Thank you for your note — I also appreciate the opportunity to express these thoughts in our fine state medical journal."

Colin B. Holman, M.D.

"It is so nice to have a thank you from the editor of the journal. I want you to know that my colleagues and I appreciate it."

R. K. Winkelman, M.D.

"I enjoyed very much the March issue of MINNESOTA MEDICINE. If I could obtain your permission, I would like to reproduce . . . In my opinion this piece of work is one of the classics we have run across from time to time."

H. Ellis Saxton, Exec. Editor
Industrial Medicine and Surgery

"I have just seen the issue. I think it is beautiful. You are to be congratulated. Your arrangement of these various rough diamonds has produced a memorable issue. I am delighted with the whole thing. Please let your colleagues on the editorial board know how much I appreciate the issue and the collaboration that has gone into it."

Raymond C. Read, M.D.
Wayne State University

"We are planning to use your editorial . . . in a forthcoming issue of *The New Physician*."

Mary Ruth Bonnell, Editorial Dept.

"This is just a note to thank you for your thoughtfulness in writing as you did about my knee injury. I am sure that my speedy recovery can be attributed equally as much to the heartwarming messages as to the expert medical attention."

Richard Nixon

"Thank you very much for your thoughtfulness in sending me a copy of the May issue of MINNESOTA MEDICINE, which contained a quotation used by my mother. I was indeed happy to read it."

Dwight D. Eisenhower

"May I thank you for sending the February issue of MINNESOTA MEDICINE. Your journal is beautifully done and I am proud to have my editorial published in it."

Raymond D. Pruitt, M.D.

"It was nice to meet you when you were here for the meeting of the American Medical Writers Association. You have done wonders with MINNESOTA MEDICINE."

Morris Fishbein, M.D.

"Congratulations on your splendid and perceptive Editor's Soliloquy 'The Physician's Gethsemane.' I am going to keep it and, if I may, I will probably quote from it from time to time. — Finally, congratulations again on the high quality of MINNESOTA MEDICINE. It is always a pleasure to read it."

Harold S. Diehl, M.D.

"Many thanks for the editorial in MINNESOTA MEDICINE. Despite our human shortcomings, ours is a great profession and playing a small role in its constant growth and progress is so satisfying. Many thanks for your continued support."

Edward R. Annis, M.D.

"I take the liberty of forwarding to you a copy of the sermon I delivered before members of the American Medical Association — it was a privilege for us to have the opportunity to be host to members of the AMA — with cordial good wishes."

C. Julian Bartlett, D.D., San Francisco

Continued

EDITOR'S SOLILOQUY

"May I once more write that MINNESOTA MEDICINE is truly blooming. There has been a continuous improvement to the point where the journal has all sails to the wind. Congratulations to you and the truly functioning board of editors."

Arthur H. Wells, M.D.

"The national recognition recently conferred . . . is but a reflection of the quality of its editorial board and the dedicated services which a dynamic editor contributes to this literary effort. A host of your professional colleagues join in this accolade."

Thomas P. Cook

"My compliments to you on the excellent edition of MINNESOTA MEDICINE. It certainly ranks as one of the outstanding state medical journals. You are to be congratulated."

Allan P. Thal, M.D.

University of Kansas

"For some time it has been on my mind to write to you and the board of editors to express my sincere appreciation—the publication itself is beautifully done. I can quite understand the recognition for excellence which has come to the journal under your direction."

John L. McKelvey, M.D.

"MINNESOTA MEDICINE has reached its all time high as a most outstanding medical journal. You and the hard working members of the board cannot be given enough credit for this achievement."

Harold W. Brunn

"Dr. Lester King, one of the editors of JAMA, spoke of a course on medical writing—and asked me if you would be good enough to send him 20 copies of one issue of MINNESOTA MEDICINE so it can be utilized in the teaching program. He felt that MINNESOTA MEDICINE was perhaps the best state medical journal."

Albert Sullivan, Jr., M.D.

University of Minnesota

"With a few extra thousand dollars, — I should think that MINNESOTA MEDICINE would be financially secure, a better journal, and a true competitor of the NEW ENGLAND JOURNAL."

W. J. Martin, M.D., Mayo Clinic

"Mr. Speaker, I would like to insert a very interesting article in the Congressional Record . . . which was referred to me by a very close friend and consultant, who has been very active in veterans affairs in my community. The article expressed in medical terms one of the major problems with which our nation is confronted — *The Gimmie Syndrome*, MINNESOTA MEDICINE 49:449, March 1966." Congressional Record, Oct. 18, 1966. Page 85370.

Hon. Joe T. Broyhill

Virginia, House of Representatives

"The publication itself is beautifully done, even for the layman. It is extremely readable and the circulation figures are impressive."

Hazel Conway, Young & Rubicam, Inc.

Librarian

"MINNESOTA MEDICINE exhibits good editing and I found much of interest—delighted to know that some doctors can write plainly and with a touch of humor."

Minneapolis Star-Tribune

George L. Peterson,

"Many thanks for your nice note. If you find my manuscript acceptable for publication in MINNESOTA MEDICINE, which has become a journal of distinction under your aegis and direction, I would like to believe that you would publish it all in one issue."

Owen H. Wangenstein, M.D.

It is to the diligent, hard-working, unselfish board members that all the credit is due. They write, they talk, and they coax manuscripts and editorials from overworked physicians wherever they can get them. They read, review, correct, stylize, edit, and re-edit unstintingly until manuscripts are about ready to come out of their ears. They forego their lunch, their coffee breaks, and their social hour in order to produce a good MINNESOTA MEDICINE. Pat yourself on the back for having such dedicated board members. It was for them that I almost broke my arm.

Carl O. Rice, M.D.

Old Doc Hess says: That woman married him for his money but she had to wait 40 years for it.

Our Senior Educators

Burtrum C. Schiele, M.D.

DR. SCHIELE'S EARLY memories emphasize Pike's Peak. He lived in Colorado Springs and went to Colorado College there for his bachelor of arts. His doctor of medicine took him to Colorado University at Denver, and he began his travels, which have grown steadily wider in scope, by taking an internship at Ancker Hospital in St. Paul. After a two-year fellowship as a Commonwealth Fund Fellow in psychiatry with Franklin Ebaugh at Colorado Psychopathic Hospital, he became assistant resident and then resident psychiatrist at Payne Whitney Psychiatric Clinic, New York. From there he went to the University of Minnesota where he has continued and is now chiefly doing research in psychopharmacology.

The Colorado mountain club's young Burtrum Schiele was the only son of a mining consultant. Whatever physical exuberance may have led him to climbing mountains, it appeared to weaken rather early in favor of wrestling with biological science. As an undergraduate, torn

Continued

between chemistry and biology, his choice moved in the direction of biology, possibly conditioned a bit by his being offered a job as student assistant in the biology department. Chemistry came to be represented at a rather low level by summer jobs at a filling station; but biology actually provided a student day's earning potential. Curiously predictive of an aspect of his much later work, he earned money for medical school expenses by collecting pollen for pharmaceutical houses. Most people collect Colorado cockle burrs with relative ease; in contrast, however, the pollen of the Colorado cockle burr is difficult to get, and among the first innovative efforts that appeared in Dr. Schiele's career was his development of new cockle burr pollen collecting methods. There was yet another early indicator of his later career when he received the first prize given by the college of medicine for achievement in clinical pathology. This prize was known as the Todd Prize, the donor being a relative of Minnesota's Todd, benefactor of the Todd Memorial Hospital, a part of the University of Minnesota Hospitals.

Later, graduating from a part-time job as desk clerk at the Colorado Psychopathic Hospital where he met the psychiatrist, Franklin Ebaugh, Dr. Schiele became the first of the Psychopathic Hospital's junior interns. Feeling a need to broaden his experience, he chose to leave Colorado to take his internship at Ancker Hospital in St. Paul. As is not uncommon, the internship experience established a relationship with one of the most attractive among Ancker's nurses, and the German strain in the Schiele family later became allied with a Scandinavian Pederson family when he married Evelyn Pederson. The Schieles have three children: two girls, and one boy. Gretchen, the elder daughter, established the Schieles as world travelers by an early interest in languages and in foreign service, spending some time in Europe where the family visited her. Ultimately she married a career state department man, and the young couple are now living in Laos. The Schieles expect to go there very soon, combining professional errands with 'round the world' travel and a visit to the young folks.

After internship Dr. Schiele returned to Colorado Psychopathic Hospital with Ebaugh for a two year residency in psychiatry. Ebaugh, who was at that time exceedingly active in American psychiatry, had been a student of Adolf Meyer, whose psychobiological orientation was particularly attractive to Schiele. Ebaugh was noted for his ability to push young scientists along, and after the two-year residency he was encouraging Schiele to leave Colorado again for further training and maturity. Ebaugh was so much a man to push his protégés along that he gave young Dr. Schiele and nurse Pederson a wedding present more than a year before they were married. In fact, typical of those times, the young pair that had met at Ancker were not finally married until they had been separated by a whole continent when Evelyn was a psychiatric nurse at Stanford University Hospital and Burt was a resident in New York with Diethelm.

Oskar Diethelm, also one of Adolf Meyer's students, represented further strong personal influence in the direction of biopsychology. Schiele continued for three years at Cornell Medical School with Diethelm and then came to the University of Minnesota in 1937 as assistant professor of psychiatry and neurology.

Dr. J. C. McKinley, who had been particularly interested and proficient in neurology, was then head of Minnesota's Division of Neuropsychiatry, at that time in the Department of Medicine. The Psychopathic Hospital had recently been established, and there was a real need for greater emphasis upon the psychiatric aspects of illness. During the earlier years at Minnesota, while Dr. Schiele continued to develop his neurological skills so that he obtained his National Board certification in both psychiatry and neurology, he nevertheless maintained the emphasis on psychiatry as his distinctive contribution during this whole period of his life. He was particularly interested in adult inpatient psychiatry and began to accept prime responsibility for this service in 1944, continuing his interest and activity until 1961 when he became principal investigator in a U. S. Public Health Service grant establishing a research unit in clinical psychopharmacology.

Dr. Schiele was one of the first psychiatrists in this region to begin clinical studies of the therapeutic effects of chlorpromazine, as reports of this drug appeared in the journals. Intrigued by his work in the area, Schiele took a quarter leave from University responsibilities to return to student status. He intensively reviewed his training in physiological chemistry and became familiar with modern structural chemistry. As a direct outgrowth of this growing interest he became, in cooperation with psychologist Gordon Heistad who is also interested and active in the behavioral correlates of pharmacological agents, the director of one of the first research units for early clinical drug evaluation sponsored by the National Institute of Mental Health. These units, as the name implies, were established to provide for early scientific evaluation of drugs before their release on the market. This new field increased so rapidly in national importance that another very long word was soon added to our vocabulary by establishment of the American College of Neuropsychopharmacology. Dr. Schiele is a charter fellow in this now well-established group.

Since 1964 Dr. Schiele has been a member of the Clinical Drug Evaluation Committee of the National Institute of Mental Health. In connection with that committee as well as in related fields, he has been much in demand for site visits in this country and abroad. His pioneering role in the clinical drug evaluation area makes his estimate of projects and settings unusually valuable. His previous experience and special training make him particularly respected among his peers because his talks and evaluations are full of information that is of direct interest and value to the practicing physician. In relationship to the research area he is particularly noted on the one hand for his emphasis on the dangers of artificial and over-controlled laboratory research unrelated to clinical application and, on the other hand, for his advocacy of carefully controlled practical studies in contrast to loose clinical evaluations.

With all his national and international activities Dr. Schiele has not neglected to fill an important role in local teaching and lecturing as well as in the encouragement of Minnesota research. He has long been a consultant to the St. Cloud Veterans Hospital; he serves on the State Medical Advisory Committee; he has established research bases in several state hospitals; and he organizes a steady flow of research within the

Continued

Psychopathic Hospital of the University. He is past president of the Minnesota Society of Neurological Sciences and of the Minnesota Psychiatric Society and has also found time for more routine committee service in Medical Sciences.

The following short bibliographic list provides a summary sample of the clinically oriented contributions that have appeared from the work of Schiele and his associates:

In conclusion I cannot forego a personal note. We all know that, however significant a man's scientific contributions may be, his role as a colleague and member of our community relates significantly to his professional achievements. I have been a neighbor and staff associate with Burt for nearly thirty years. This association has served to establish an invariable record of integrity and loyalty in the interpersonal life in which we have been participants. For most of us it is trite and in some way embarrassing to enumerate examples and to marshall adjectives when we wish to particularize the virtues of our friends. However, I am confident that those who are also privileged to know and appreciate these qualities in Burt and "Pedey" can easily supply the merited words of praise. I can only add my warm endorsement from long and intimate association.

Starke R. Hathaway, Ph.D.
Minneapolis, Minnesota

**Oliver Wendel Holmes, M.D.
To the Young Practitioner**

Ask the wisest practising physician you know, what branches of science help him habitually, and what amount of knowledge relating to each branch he requires for his professional duties. He will tell you that scientific training has a value independent of all the special knowledge acquired. He will tell you that many facts are explained by studying them in the wider range of related facts to which they belong. He will gratefully recognize that the anatomist has furnished him with indispensable data, that the physiologist has sometimes put him on the track of new modes of treatment, that the chemist has isolated the active principles of his medicines, has taught him how to combine them, has from time to time offered him new remedial agencies, and so of others of his allies.

But he will also tell you, if I am not mistaken, that his own branch of knowledge is so extensive and so perplexing that he must accept most of his facts ready made at their hands. He will own to you that in the struggle for life which goes on day and night in our thoughts as in the outside world of nature, much that he learned under the name of science has died out, and that simple homely experience has largely taken the place of that scholastic knowledge to which he and perhaps some of his instructors once attached a paramount importance.

Where to Look

Mitral stenosis may be concealed under a quarter of a dollar. It is the most difficult of all heart diseases to diagnose. — Osler

Curbstone Consultation

Ligation of Hepatic Artery

QUESTION: I have heard conflicting statements as to the mortality associated with ligation of the hepatic artery in humans. How serious actually is this injury when it occurs accidentally in patients with normal livers?

ANSWER: At one time it was felt that the mortality associated with accidental ligation of the hepatic artery would run about 60%. Such figures were based on observations made in the pre-antibiotic period and included all cases of hepatic artery ligation. On retrospectively reviewing many of the cases on which such a mortality figure was based it is now apparent that death was undoubtedly due in many instances to causes unrelated to the arterial ligation.

More recent observations would indicate that ligation of the hepatic artery or one of its branches is not ordinarily fatal in an otherwise uncomplicated case. When this injury does occur, however, attention must be given to preventing deleterious influences from secondary factors, such as shock and sepsis. Such added factors could diminish the collateral flow or increase the hepatic oxygen need, thereby leading to unfavorable consequences.

Harold D. Kletschka, M.D.
Syracuse, New York

Sarcoidosis

*QUESTION: Is the presence of fever of prognostic significance in a patient with sarcoidosis?**

ANSWER: Perhaps forty per cent of patients with sarcoidosis will have fever attributable to the disease. Negroes have a higher incidence than white patients. Although fever generally may not be thought of as a significant feature of sarcoidosis, in one study thirty-two per cent of such patients exhibited a temperature elevation between 101° to 103° and ten per cent had temperature elevations above 103° F. The occurrence of fever is not dependent on the extent or localization of the disease although erythema nodosum is more common among febrile patients. The pathogenesis of the fever in sarcoidosis is unknown. It is unreliable to prognosticate on the basis of an associated fever. Although hospitalization may be more prolonged in febrile cases this difference may be attributable to delay in diagnosis because of inability to appreciate the association of fever with sarcoidosis.

The Viewing Box

Chest Pain with Negative Chest Roentgenogram

A 35-year-old white female entered the Outpatient Department of the St. Paul-Ramsey Hospital complaining of nervousness and anxiety. She also complained of a single episode of shortness of breath without chest pain. There was no history of expectoration, hemoptysis or hoarseness, but she had previously noted some dysphagia. She had been delivered of a normal pregnancy one month previously and following this had been placed on a mild tranquilizing agent and "birth control pills." Examination disclosed some questionable diminution of breath sounds in the right lower lobe area; otherwise no abnormal physical or laboratory findings were present. After one hour she was discharged from the Outpatient Department.

Three days later she was admitted to the hospital complaining of chest pain. Again physical examination was negative except for a pulse rate of 108 per minute. The chest x-ray was considered negative (Figure 1). She was placed on strict bed rest and heparinized. Against orders she got up to go to the bathroom and became dyspneic and cyanotic and collapsed. No blood pressure reading could be obtained, and her pulse was very weak and fast. Her blood pressure was artificially elevated and a chest roentgenogram plus a lung scan using I^{131} tagged macro-aggregated serum albumen was obtained.

What is your diagnosis? (See next page.)

Figure 1

DIAGNOSIS: Pulmonary embolism.

The interpretation of the lung scan indicated multiple areas of pulmonary embolism of the right upper and lower lobes and totally of the left lower lobe (Figure 2). An immediate catheterization of the right side of the heart was done and a pulmonary angiogram obtained. The pulmonary artery to the left lower lobe was completely occluded (arrow, Figure 3). Comparison with the admission chest film disclosed a cut-off of the arterial supply to the left lower lobe on that film (Figure 1 and arrow, Figure 2). Following digitalization she had an immediate plication of the inferior vena cava.

Figure 2

Figure 4

Figure 3

Followup chest roentgenogram and lung scan (Figure 4) after one week showed improvement in lung vascularization and some resolution of the infarcted areas. (Lung scans are superimposed on the admission chest film for comparative purposes.)

She was discharged on a regimen of Coumadin.

Medical Seminar

Hereditary Hemorrhagic Telangiectasia

Rendu-Osler-Weber Syndrome

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

THE SYNDROME of hereditary hemorrhagic telangiectasia (Rendu-Osler-Weber disease) is characterized by the triad of multiple telangiectases, hemorrhage, and a familial history. The telangiectases with or without hemorrhage can involve almost any organ. Although not very common, the disease must be considered in the differential diagnosis of unexplained bleeding from any body organ. Epistaxis is the most frequent bleeding problem.

It is not known who first wrote of this disease. Babington,¹ and Legg,² both in the last half of the 19th century, noted the familial occurrence of epistaxis. A number of Legg's patients had cutaneous lesions, and perhaps a few of them were afflicted with hereditary hemorrhagic telangiectasia. Rendu³ recognized the association between epistaxis and multiple angiomas or telangiectases when he presented a case in Paris in 1896, the familial character of which was appreciated by Rendu, as his patient's mother, father, and brother had repeated hemorrhages. Both Rendu³ and Legg² considered the familial bleeding to be atypical hemophilia or pseudohemophilia. Osler⁴ established this syndrome as a clinical entity by separating it from the large and confused group of hemorrhagic diseases, and he documented the clinical features in a manner that remains a classic. Weber⁵ elaborated on the clinical and genetic features of the disease; but it was Hanes,⁶ in 1909, who de-

tailed the histopathology of the lesions and proposed the name hereditary hemorrhagic telangiectasia. Hanes has been called the forgotten man in what has come to be known as Rendu-Osler-Weber disease. Weber's⁷ later work, in 1924, called attention to the clinical spectrum of the disease that ranges from familial epistaxis to the full-blown syndrome of familial epistaxis with widespread telangiectases. He also included familial hematuria, familial gastrostaxis, and familial hemorrhoids as manifestations of the same developmental defect.⁸

Goldstein^{8,9} reviewed reports in the literature up to 1931 of the estimated 90 to 95 families with 500 to 550 members who had the disease. He emphasized that bleeding from most organs, including the eye and brain, could be associated with telangiectasia. Epistaxis was noted to be the most common bleeding problem.

Clinical Features

The principal feature of the disease is hemorrhage from telangiectatic lesions of the affected organ. Epistaxis is the most frequent symptom, and although epistaxis can occur in infancy, it usually begins in childhood.¹⁰ A decrease in frequency of nosebleeds or even a remission of all symptoms during adolescence or pregnancy has been observed.^{10,11}

The cheek, lips, mouth, tongue, nasal sep-

Continued

tum, inferior turbinates, and fingers are the most apparent sites of the telangiectases. Lesions also may be found on the trunk and hands and beneath the fingernails. During childhood and adolescence, the telangiectases are obscure or absent; they tend to become more prominent and increase in number between the ages of 35 and 50 years. The skin is involved in all but a very few patients with hereditary hemorrhagic telangiectasia. It may be necessary to scan the entire epidermis very carefully in some patients or family members to find one or two tiny lesions. The telangiectatic blemishes, however, are usually obvious. Serious hemorrhage from the skin is rarely a problem because of accessibility of the lesions and the protective layer of stratified squamous epithelium.

Most of the patients come to the physician because of epistaxis. Some patients with nosebleeds probably are treated without the underlying disease being recognized. Bleeding often occurs daily and can be triggered by a cough, sneeze, or slight trauma. At times, epistaxis begins while the patient is lying quietly or even sleeping. Saunders¹² described one patient who required more than 2,000 blood transfusions, and death from epistaxis has been reported.¹³ At the other extreme, the bleeding may be only a minor ooze that occurs at infrequent intervals and is easily managed by the patient himself.

Telangiectases of the anterior nasal septum, inferior turbinate, and floor of the nose are particularly vulnerable to slight trauma, with resultant hemorrhage. Patients often are seen with septal perforations from repeated packing or cautery.

The gastrointestinal tract is another common site of telangiectases. Gastrointestinal lesions may be present and bleed in individuals who do not have obvious cutaneous or oral lesions.^{14,15} The more frequent causes of gastrointestinal bleeding, for example, peptic ulcer, can coexist in patients with visceral, nasal, or cutaneous telangiectasia.

The association of pulmonary arteriovenous fistula in individuals with hereditary hemorrhagic telangiectasia is well documented. Hodgson and Kaye¹⁶ reported that

49% (17 of 35) of their patients with arteriovenous fistula had a family history of hemorrhagic telangiectasia and 66% (23 of 35) were found to have telangiectasia on examination. They advise alertness to the development of arteriovenous fistula in persons in a family with hemorrhagic telangiectasia and recommend that these individuals have periodic chest roentgenograms.

Other less common sites of lesions are the brain, urogenital tract, and eye. Bird and associates¹⁷ found that approximately 10% of patients with hereditary telangiectasia did not hemorrhage.

The telangiectases of the skin and mucous membranes take three forms: (1) tiny, pinpoint, purplish red spots most often found on the face and hands and easily overlooked; (2) flat spider forms, the most common lesions, which resemble crushed spiders and are cherry red and two to three mm. in diameter, and (3) large, nodular telangiectasia, the lesion seen in older patients in whom a nodule the size of a split pea arises from the center of a flat spider form. All three forms are nonpulsatile, blanch with pressure, and bleed in an arterial fashion when traumatized. Monroe and Spencer¹⁸ emphasized that children in affected families usually have small spider-type cutaneous lesions that can be difficult to find. Failure to recognize these early lesions probably accounts for the rare diagnosis of hemorrhagic telangiectasia in children in the first decade of life. This phenomenon of occult cutaneous lesions may also explain the so-called "skipped generations" or atavism postulated by Fitz-Hugh.¹⁹

Laboratory Findings

Hypochromic, microcytic anemia almost always occurs in patients with bleeding lesions. Hemoglobin levels of 4 gm. are commonly reported.¹³ Results of tests of the bleeding and coagulation mechanism are normal. Abnormal results of the tourniquet test have been reported, but it is probable that the tourniquet merely brings into prominence the very tiny telangiectases that were not previously noticed and which were misinterpreted as being petechiae.

Histopathologic Features

Under the microscope, dilated endothelial lined spaces can be seen. Hanes⁶ noted an absence of muscle and elastic tissue in the walls of the superficially dilated vessels. This observation, however, has been disputed by Bean.²⁰ In the skin, the endothelial spaces lie immediately beneath the epidermis; the papillary layer of the corium is thinned, and the stratum germinativum is absent. In the nose, the dilated endothelial spaces lie just beneath the pseudostratified columnar epithelium.

Heredity

The hereditary features of hemorrhagic telangiectasia have been thoroughly studied.^{8-10,17} The disease is transmitted as a Mendelian dominant gene, with complete penetrance and no sex predilection. A positive family history of repeated hemorrhage or skin lesions or both is found in most patients. Stecker and Lake¹¹ recorded a positive family history in 86% of their patients. The finding of the 14% who did not have a positive family history was explained by the fact that most relatives were asymptomatic and that the disease was not recognized. In a study of the 491 descendants of a polygamous Utah pioneer, Dolowitz¹⁰ traced the disease through six consecutive generations. A single case is recorded of a progeny of two parents with hemorrhagic telangiectasia by Snyder and Doan.²¹ The infant died within three months from bleeding of multiple organs including the skin. They postulated that the homozygous state is lethal.

Treatment

A review of the multitude of treatments proposed for hereditary hemorrhagic telangiectasia is a study of alternating enthusiasm and disappointment. In certain instances there appears to be no lasting method to stop the bleeding. Old lesions reappear after vigorous attempts to destroy them, or new ones appear in their place or nearby. Stecker and Lake¹¹ caution conservatism "... only enough treatment, that is, to control the symptoms within tolerable limits without attempting drastic therapy

which might possibly aggravate the symptoms."

Treatment has involved three basic approaches: (1) local therapy in an attempt to control the bleeding, (2) systemic medications in the hope of altering the susceptibility of the lesions to bleeding, and (3) treatment of the anemia that is invariably part of the disease.

Local Treatment

Epistaxis, the major clinical problem, has been managed in numerous ways. Mechanical packing with cotton, absorbable gelatin sponge (Gelfoam), gauze strips of petrolatum (Vaseline), and various balloon devices may provide temporary assistance. There probably is some merit to the patient's carrying a self-inflatable balloon device, which helps him achieve some peace of mind, knowing that he is not totally dependent on assistance from others when his nose bleeds. The use of packs soaked in Russell's viper or moccasin snake venom is of historic interest. The nasal chambers of a number of patients have undergone partial necrosis from such packs only to later develop bleeding sites beyond the damaged area. Electrocautery has its advocates,²² but even the most enthusiastic technicians admit the frustration of finding new lesions adjacent to the recently cauterized nasal membrane. Septal perforation is a common sequela to extensive electrocautery or chemical cautery. Other local methods tried without uniform success include direct nasal implants of radium; conventional irradiation; radioactive cobalt irradiation; surgical removal of the entire nasal septum; submucous resection; ligation of the external carotid, internal maxillary, and ethmoidal arteries; and turbinectomy.

The recent innovation of internasal skin grafting as advocated by Saunders^{12,23,24} and others^{11,25} is a promising contribution to the local management of the problem of epistaxis of this generalized disease. The principle of grafting is to substitute tough squamous epithelium for the more fragile respiratory epithelium on the vulnerable

Continued

areas of the anterior nasal passages. The original procedure of Saunders,²³ which involved grafting the anterior septum, has been expanded to the grafting of the anterior lateral wall, the floor of the nose, the upper lateral cartilage area, and even the entire septum. The results of the various grafting techniques are encouraging, but severe epistaxis has not always been stopped. Saunders¹² has observed that most of his patients bleed after dermatoplasty but that bleeding is generally much less than before. In contrast, Stecker and Lake¹¹ admit that the bleeding of two of their 12 patients was greater after grafting. They believed that the drying of the nose which follows skin grafting contributes to further bleeding from lesions posterior to the grafted area; these posterior lesions were not present or were not apparent at the time of dermatoplasty.

Patients with pulmonary arteriovenous fistula should have the lesions removed surgically, particularly if there are only one or two. The unoperated patient is subject to the complications of hemothorax, heart failure, and brain abscess.

Systemic Medications

A large number of systemic medications have been advocated in the management of hemorrhagic telangiectasia. Most of the drugs were directed to the control of the bleeding by lessening coagulation defects or improving vascular permeability: problems that in most cases do not exist. Vitamins K, P, and C, snake venom, rutin, and corticosteroids have all failed to decrease the troublesome epistaxis. Koch and associates²⁶ and Harrison^{27,28} have reported success with the use of orally administered estrogens in the management of epistaxis. Harrison has biopsied the nasal mucosa after prolonged administration of ethinyl estradiol and demonstrated that the usual nasal respiratory epithelium was replaced by stratified squamous epithelium. The desired result of a decrease in frequency and severity of the nosebleeds was obtained in all 20 patients within one to three weeks of estrogen treatment, but unfortunately there was a prompt

relapse after therapy was terminated. Epistaxis is the only form of hemorrhage that has been controlled by the administration of estrogens, but there are obvious drawbacks, particularly in the male, to prolonged estrogen therapy. Saunders²³ stated the belief that estrogens are best used only in patients that continue to bleed after dermatoplasty.

Treatment of the Anemia

The correction of anemia from blood loss by the use of orally administered iron and by transfusion remains an important part of the management of this disease.

The handling of the individual patient necessarily combines the various approaches as needed. Correction of the anemia, local lubrication of the nasal membranes to prevent drying as well as use of pledgets, packs, inflatable balloons, and electrocautery of single troublesome lesions should provide a tolerable existence for most patients. When epistaxis continues to be a difficult problem, split-thickness skin grafts to the anterior septum, anterior tips of the inferior turbinates, and floor of the nose are recommended. The judicious use of orally administered estrogen after grafting seems reasonable.

Prognosis

Hereditary hemorrhagic telangiectasia varies from completely asymptomatic individuals to those with diffuse telangiectases and repeated massive hemorrhage. In most cases, the condition lies between these extremes.

Spontaneous, complete remission of symptoms has been reported.¹¹ Two of the three remissions noted by Stecker and Lake¹¹ occurred during pregnancy and persisted after delivery. Hereditary hemorrhagic telangiectasia usually is compatible with life but at times offers a miserable existence. Death, when it does occur, is usually due to profound anemia or shock or to the hazards of repeated transfusion. Houser¹³ estimates a mortality rate of 4% directly attributable to the disease.

Summary

Hereditary hemorrhagic telangiectasia is

a well-defined clinical syndrome characterized by the triad of bleeding from multiple sites (particularly the nose), cutaneous or oral lesions, and a positive family history. The bleeding can be very trivial or incapacitating. The full clinical spectrum can be seen in the same family. Epistaxis is the most frequent bleeding problem.

Treatment should involve the least drastic

procedures necessary to control the symptoms. Iron replacement or transfusions are usually necessary. Orally administered estrogens probably have some value, particularly when they are given after nasal dermatoplasty in patients who continue to bleed from the nose. Single pulmonary arteriovenous fistulas are best resected to avoid complications.

Green Medicinals

Herbs for the Brain

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them. For improving the brain and its potential, herbal repertories include such simples as amaranth, dill, ivy, lachnanthes, mugwort, rosemary, strumonium, and wormwood — with the following recipe for a savory rosemary sauce:

Rosemary Sauce

Into one and a half ounces of butter throw a very finely chopped sprig of rosemary and fry for one minute. Add an ounce of flour and mix it well in the butter. Then add a pint of stock, the juice of a lemon and a tablespoon of anchovy sauce. Boil well together for ten minutes.

— C. F. Leyel, Green Medicine

Book Reviews

Something is learned every time a book is opened. — Chinese proverb

EARLY MANAGEMENT OF ACUTE TRAUMA —
Nahum, C. V. Mosby, Publication Date 7-12-66,
Price \$21.00.

This subject which is so important for young physicians to grasp at the earliest possible time in their practice is very difficult to cover with completeness in 326 pages. This text, which is the work of 21 different authors, suffers somewhat from its brevity, yet certain of the chapters are particularly good — notably that on genitourinary system injury.

The broad principles of trauma management are well delineated and the overall purpose of providing a practical medical background for those who are to care for the traumatized patient is achieved. The book, however, will be of most value to interns and residents.

Harrison H. Farley, M.D.
Minneapolis, Minnesota

APPLIED HYPNOSIS AND POSITIVE SUGGESTION — G. A. Ulett and D. B. Peterson, C. V. Mosby Company, St. Louis, 1965. 134 pages, \$8.50.

This primer is written in an easy to read style with very little verbiage. It should be of interest to physicians, dentists and others of the healing arts team wanting to learn methods, limitations and difficulties of hypnosis, as well as for more casual reading for interest's sake. The format is comfortable, arranged with subtitles for the reader's benefit and ready grasp. Would that more topics were presented in this manner! Two transposed sentences will likely be correctly arranged in later printing.

The authors "look upon hypnosis as the useful extension of the doctor-patient relationship." Twenty per cent of patients can be hypnotized to the stage of trance. Ulett and Peterson consider phenomena short of this as hypnotic, since the borderline is not easily defined. They have broadened the definition of hypnosis by including the stronger aspects of response to suggestion. One gets the impression that so long as the desired symptom relief or behavioral modification is achieved, some element of hypnosis has occurred.

Their discussion of the use of enthusiasm and positive suggestion, positive statements and words rather than those with more negative connotations indicates an approach which physicians can use to better advantage. They label this as part of the art of medicine, which is true as long as it is used intuitively as in the past. Now that suggestion can

be used with awareness, understanding and replication, it could well be considered as part of the science of medicine.

Attention to the positive approach in the physician-patient relationship is in good order whether described in the hypnosis model, response-reward construct, interactional psychology, or some other approach. This has merit as an intrapsychic process as well.

The authors dispel the aura of "evil mysticism" and the "unknown" and fearsome danger often associated with hypnosis. They offer adequate precautions, such as a rule that each physician should stay within the limits of his training. For example, an obstetrician using hypnosis should not use it to treat psychosis in a patient.

They discuss the history, theories, and nature of hypnosis, its use for symptom removal, pain relief, recovery of the memory of forgotten incidents, analgesia and anesthesia. A variety of areas of use are described by chapter titles: the use of hypnosis in medicine, surgery, psychiatry, obstetrics, auto-hypnosis, hypnosis in habit control, and hypnosis in children. They present this as a means to an end and recognize the merit of adjunctive therapies. Other chapters deal with methods of inducing, deepening and terminating hypnosis, with emphasis on proper selection of patients based on adequate diagnostic considerations. They describe physical and verbal components of the process, the direct approach, and the methods of obfuscation. Interestingly, they talk of the "double blind" as if it were a common term. (A reference to Bateson, G., Jackson, D. D., Haley, J., Weakland, J. H.: "Toward a Theory of Schizophrenia," Behavioral Science, 1:251-264, 1956 should be included in the bibliography.)

The hypnotic process is a complementary interaction in which the physician seems to be in control. The authors maintain, however, that the physician is only making use of the patient's response patterns and that in actuality the patient is in control of what he does.

Their thesis throughout is supported by cogent, concise examples. Their enthusiasm and positive presentation is understandable, but perhaps a little over-selling. The reader needs be wary lest Ulett and Peterson cast a spell over him, under which he would feel impelled to practice hypnosis.

FIGHTING CANCER WITH FILMS...

...is not news. What's news is that we've embarked on the most ambitious film program *for professional medical audiences* ever launched against a single disease. A half-million dollar film project is underway—with technical advice from the nation's leading medical authorities.

Five of these films are available now—

CANCER IN CHILDREN, DIAGNOSIS AND MANAGEMENT OF CANCER OF THE COLON AND RECTUM, ORAL CANCER, NURSING MANAGEMENT OF THE PATIENT WITH CANCER, and THE DENTIST AND CANCER. The balance will be released in 1967-1968.

As pioneers in the usage of medical films, we know their value as teaching tools. Our Units across the country know, too. Films are a vital part of their professional educational programs. We hope you will contact *your* local ACS Unit about this outstanding new series.

AMERICAN CANCER SOCIETY 

Clinical Path Conference

Leuko-Erythroblastic Anemia in Gastric Carcinoma

Dr. Robert Strom:

Case Report

A 38-year-old white female had noted intermittent upper abdominal distress occurring between meals and relieved by milk and antacids for approximately two years. For five weeks epigastric distress had increased in severity and a constant, aching pain had developed in the left hip. A prepyloric gastric ulcer was demonstrated on the upper gastrointestinal series. Epigastric pain and persistent vomiting necessitated the patient's hospitalization. Multiple purpuric lesions of the skin were present on physical examination. The serum amylase was 68 Symogi units. Two units of whole blood were transfused.

The patient was transferred to Hennepin County General Hospital, because of the onset of progressive abdominal distension. There was a history of a ten-pound weight loss over the past month. Medications included aspirin compound, phenobarbital, Probanthine and Darvon Compound.

She presented as a young white female in moderate distress with multiple skin ecchymoses. Blood pressure 130/80, pulse 100/min., temperature 99.6° Fahrenheit, weight 134 pounds. Auscultation of the heart revealed a soft systolic ejection murmur. The lungs were clear to auscultation and percussion. The abdomen was slightly distended and hypertympanitic. Bowel sounds were absent, and there was a diffuse abdominal tenderness, particularly in the area of a midline scar.

Laboratory studies included a hemoglobin of 9.8 grams %, white blood cell count 3,700 per cubic millimeter with neutrophils 71%, lymphocytes 26% and eosinophils 3%. The hematocrit was 27% and the prothrombin time 19.8 seconds. The direct platelet count was 26,000. The bleeding time was greater than ten minutes and the clotting time 17 minutes. A direct and indirect Coombs' test were negative. The fibrinogen level was reported as normal. Blood electrolyte studies showed a serum sodium of 139 mEq/L. per liter, potassium 3.5 mEq/L. per liter, Co_2 28 mEq/L. per liter, and chlorides 94 mEq/L. per liter. Blood urea nitrogen was 11 mg. % and the blood sugar 113 mg. %. Examination of the peripheral blood smear revealed increased red blood cell polychromasia and occasional nucleated red blood cells. The plasma hemoglobin was negative. Serial stool guaiacs revealed no occult blood. Urinalysis showed a specific gravity of 1.015, pH 8, albumin trace, and no sugar. Microscopic examination of the urinary sediment revealed 150 red blood cells and 45 white blood cells per high power field. A flat plate of the abdomen showed multiple air-filled loops of bowel.

A barium enema failed to show evidence of colon obstruction. Several transfusions of whole blood and platelet-rich plasma were given on the first hospital day. Repeated transfusions were necessary to maintain the hemoglobin at a level of 10 grams %. An operation was performed on the second hospital day.

Continued

Fig. 1 — Upper gastrointestinal series of x-rays showing gastric ulcer indicated by arrow.

Discussion

Dr. Robert McAllister*:

I am happy to be here today to discuss what appears to be a straightforward case initially, but becomes somewhat more complicated as the protocol develops. It seems to me that early in the protocol the history is quite compatible with an ordinary gastric ulcer. This relatively young woman had a two-year history of abdominal pain, relieved by taking milk and antacids. Her initial hospitalization with intractable pain and vomiting appears to represent some type of gastric outlet obstruction. The patient was then admitted to this hospital after abdominal distension developed. The abdomen was silent and diffusely tender. An adynamic ileus could be associated with the abdominal tenderness and this does not necessarily mean that a peritonitis was present.

X-rays

Dr. Mario Pleigo:**

The initial roentgenogram of the chest taken at the outside hospital is essentially normal with no active pulmonary disease. Several minute radio-dense shadows are seen on the films of the pelvis, involving the ischia and upper femora. The nature of these densities is not clear but they could represent bone islands or osteoblastic metastases. The upper G.I. series shows a persistent collection of barium on the greater curvature of the stomach (Figure 1). There are multiple radiating folds from

*Department of Internal Medicine, Assistant Dean, University of Minnesota Hospitals.

**Associate Radiologist, Department of Radiology, Hennepin County General Hospital.

this collection of barium and all other radiographic findings suggest a benign gastric ulcer. The abdominal flat plate reveals gas-filled loops of small and large bowel distributed throughout the abdomen. A diffuse ground-glass density is also seen throughout all the films. This suggests an adynamic ileus with a superimposed accumulation of ascitic fluid.

Dr. McAllister:

It is important to know at this point that the patient remained distended despite nasogastric suction. Bowel sounds were absent and later a barium enema showed no evidence of large bowel obstruction. These factors point toward a diagnosis of adynamic ileus rather than a mechanical bowel obstruction. As a cause of adynamic ileus we must consider hypokalemia secondary to vomiting. The serum potassium is at the lower level of normal; however, it may not be an accurate reflection of the total body potassium. Another possible etiology to be considered in view of her purpuric lesions and hematuria would be intraabdominal or retroperitoneal bleeding. Perforation of the gastric ulcer with chemical or bacterial peritonitis or associated pancreatitis may present with an adynamic ileus. The presence of necrotic bowel secondary to arterial or venous occlusion or due to a diffuse vasculitis might also be considered.

The predominant initial laboratory findings were anemia, thrombocytopenia and an abnormal prothrombin time. The bleeding time may be expected to be prolonged in the presence of thrombocytopenia. The blood smear showed minimal hypochromasia; however, since multiple blood transfusions were administered shortly after hospitalization this finding may have been altered. Do we have any idea about this patient's history of pregnancy?

Dr. Gerald Onstad*:

The patient had had three previous pregnancies and had delivered three normal infants without complication.

Dr. McAllister:

The anemia present on admission could represent chronic intermittent bleeding from the gastric ulcer or a mild iron-deficiency anemia due to her previous pregnancies. What is not compatible with a bleeding gastric ulcer, of course, is the thrombocytopenia, the elevated prothrombin time and purpura in the presence of guaiac negative stools.

Thrombocytopenia

Thrombocytopenia may be conveniently divided into the idiopathic variety or a secondary thrombocytopenia associated with a large group of miscellaneous factors, including chemical and physical agents which might depress the platelet count. Considering first the chemical agents, she certainly was exposed to a number of things that have been reported to be associated with thrombocytopenia. Salicylates or phenobarbital could cause thrombocytopenia on a hypersensitivity basis. There appears to be no evidence of physical agents or x-ray treatment which might have lowered the blood platelets. An idiosyncratic reaction secondary to salicylate ingestion could give this picture.

*Department Internal Medicine, Hennepin County General Hospital.

Continued

Another large category of diagnoses known to cause thrombocytopenic purpura are the various hematopoietic disorders, such as leukemia, aplastic anemia, or pernicious anemia. One of the hallmarks of vitamin B-12 or folic-acid deficiency is thrombocytopenia. Certain hemolytic anemias may also be associated with thrombocytopenia. We would not likely consider any splenomegalic disorders here since the spleen was not noted to be palpable. Thrombotic thrombocytopenic purpura would also have to be considered because of the anemia, low platelet count and purpura. Certain viral infections are also associated with thrombocytopenia.

Consumption Coagulopathy

With the prolonged prothrombin time we would have to think of any disease that might lower the coagulation factors 5, 7 and 10, prothrombin or fibrinogen. Since abnormalities in any one of these factors are reflected in the one-stage prothrombin time, the presence of hepatic disease might be suspected. An excess of a circulating anticoagulant could interfere with clotting parameters. Congenital deficiencies of factors 5, 10 or fibrinogen would certainly have been detected in the patient's family history. Liver disease alone may be associated with a prolonged prothrombin time. It would be important to know whether or not this patient had received any antibiotics in the recent past?

Dr. Onstad:

As far as we know the patient had received no antibiotic medication.

Dr. McAllister:

Antibiotic therapy is known to enhance a Vitamin-K deficiency; however, this seems to be excluded by the history. The administration of salicylates in the presence of liver disease, could well induce depression of the clotting factors. A penetrating posterior gastric ulcer leading to a pancreatitis might liberate coagulation factors, particularly thrombin, into the blood stream and cause the clotting mechanism to be accelerated. In most instances the clotting factors would be used up because of diffuse intravascular coagulation, primarily effecting the small blood vessels. The normal amylase observed is against pancreatitis, but does not exclude that diagnosis. The normal fibrinogen level also makes a consumption coagulopathy a more remote possibility.

Collagen Diseases

My initial impression on reviewing the protocol was that of a collagen disease with thrombocytopenia and later pancytopenia associated with a gastric ulcer, an ileus and possibly a diffuse vasculitis. In particular we might mention collagen diseases giving rise to hypersplenism and particularly lupus erythematosus. The spleen was not palpable, however, in this lady, though the abdominal distension could have masked an enlarged spleen. We would like very much to consider a single disease process being responsible for all of the physical and laboratory findings. Henoch-Schoenlein purpura would be a possibility since the platelets may be low in some of these individuals, particularly with an associated allergic type vasculitis. Thrombotic thrombocytopenic purpura could explain many of the findings; however, the patient showed no hemolytic anemia or central nervous system findings. She was also afebrile, and

this makes thrombotic thrombocytopenic purpura an unlikely explanation for this woman's problems.

Leuko-Erythroblastic Anemia

The peripheral blood smear which Dr. Trucker kindly provided revealed a leukopenia and a leuko-erythroblastic reaction. There were many immature granulocytes and myelocytes present in the peripheral blood, together with a number of circulating normoblasts. In addition to low platelets and anemia, we now have the problem of the differential diagnosis of a leuko-erythroblastic reaction. This reaction is seen with aplastic anemia, atypical leukemia, osteosclerosis and infiltrative processes of the bone marrow, such as metastatic carcinoma.

Gastric Carcinoma

With the history of gastric ulcer and the findings on the films of the pelvis, we would have to think of gastric malignancy. There was no radiologic evidence to support the diagnosis of gastric cancer. Nonetheless we must think of an occult gastric cancer in a patient with symptoms of increasing intensity, not relieved by routine ulcer management. Approximately 10% of gastric malignancies are found in patients below the age of 40 years, and so age does not help differentiate a benign from a malignant gastric ulcer. Other possible primary sites in this woman would include a carcinoma of the breast or ovary. A renal cell carcinoma could not be excluded, particularly in the presence of hematuria. The presence of leuko-erythroblastic anemia and a gastric ulcer makes me favor the diagnosis of gastric carcinoma with bone marrow involvement. "I think a bone marrow was the operation performed at the end of the protocol."

Dr. Robert McAllister's Diagnosis

1. Gastric carcinoma with bone marrow metastases.
2. Leuko-erythroblastic anemia due to bone marrow infiltration.

Pathological Discussion

Dr. Earl B. Trucker*:

The peripheral blood findings on admission, and particularly the profound thrombocytopenia, led to considerable discussion in our department. The spacing of the red blood cells on the peripheral smears suggested a moderate anemia; however, these cells appeared normochromic and normocytic. Considerable polychromasia was present and the red cells showed minimal poikilocytosis. Numerous Howell-Jolly bodies were encountered on the peripheral smear, together with occasional target cells. On counting 100 white blood cells, three to four circulating nucleated red blood cells were encountered. An example of the circulating normoblasts is seen in Figure 2. In addition, other occasional circulating cells were seen with a loose chromatin pattern and a small amount of deep blue cytoplasm. These cells could represent circulating tumor cells or so-called "Turk-irritation" cells. An example of such a cell is seen in

*Associate Pathologist, Hennepin County General Hospital. Dr. Trucker died of Hodgkins disease on November 26, 1966.

Continued

Figure 3. The blood platelets were markedly decreased and on many oil immersion fields no blood platelets were encountered. A leukopenia was present together with a shift to the left in the neutrophilic series. Many neutrophilic band forms showed toxic granulations and Dohle bodies.

Fig. 2 — Circulating orthochromatic normoblast with pyknotic nucleus $\times 100$.

Fig. 3 — Turk-irritation cell with abundant blue cytoplasm and loose chromatin network in nucleus $\times 100$.

Fig. 4 — Metastatic signet-ring carcinoma to bone marrow sections — mucicarmine stain $\times 100$.

Dr. McAllister is quite correct in his assumption that the operation performed was a bone marrow examination. The direct smears of the bone marrow appeared slightly hypocellular with a myeloid erythroid layer of 7% and a red cell volume of 25%. The direct smears of the bone marrow showed more tumor cell clumps than I have ever seen. In most bone marrows I have reviewed, only a few carcinoma cells are seen and you are quite fortunate to identify them. The tumor cells here are not forming glands, but they are definitely of the signet-ring variety. Metastatic carcinoma to the bone marrow is the obvious explanation for the leuko-erythroblastic anemia. An example of the signet-ring cells, as seen on bone marrow aspiration, is presented in Figure 4, stained with a mucicarmine stain. Leuko-erythroblastic anemia was first well described by Vaughn¹ and the most common cause of that condition is an infiltration of the bone marrow by metastatic carcinoma. The association of thrombocytopenia with this syndrome has been documented in two similar cases recorded in recent years in the *New England Journal of Medicine*.^{2,3} In both instances a diagnosis of carcinomatosis was not made during life and both gastric lesions were initially missed on autopsy examination. Sections of areas of superficial gastric erosion verified the presence of signet-ring cells, infiltrating the submucosa of the stomach. Although in all likelihood the stomach was the primary source of the metastatic carcinoma in the bone marrow, we cannot give absolute confirmation since no autopsy was performed in this case.

Pathological Diagnosis

1. Metastatic adenocarcinoma to the bone marrow, stomach probably primary source.

2. Leuko-erythroblastic anemia, due to bone marrow infiltration by tumor.

Grand Rounds

*Pulmonary Sarcoidosis**

DOUGLAS KJELLEN, M.D.
Medical Resident

Historical

The first description of sarcoidosis was made in 1875 by Jonathan Hutchison, who observed the granulomatous lesions on the skin of a patient and called the disease "Mortimer's Malady." In 1889 Besnier described a similar case which he called "lupus pernio," thinking the skin lesions were a form of tuberculosis (*lupus vulgaris*). In 1899 Caesar Boeck, a Norwegian physician, reported the first anatomic and clinical description of systemic sarcoidosis. In 1914 Schaumann showed that the diseases previously described by Besnier and Boeck were identical and that sarcoidosis was primarily a disease of the lymphoid system.

Since the first description of sarcoidosis, our concept of the disease has broadened from that of a disorder of the skin to a widely disseminated disease capable of involving all organ systems of the body and producing many hematologic, serologic and biochemical abnormalities.

Pathogenesis and Epidemiology

The pathogenesis of sarcoidosis is difficult to relate in the absence of a known etiologic agent. The disease is essentially worldwide in distribution, the highest incidence being reported in Sweden where up to 140 cases per 100,000 population occur in certain rural forested areas.¹ The heaviest concentration in the United States is in the southeastern states. There is an undisputed predilection for Negroes, among whom the disease has been reported to occur from 15 to 18 times as frequently as among whites. The peak prevalence of sarcoidosis is in the third decade of life. Although its occurrence is infrequent in the extremes of life, the diagnosis should be considered in older patients. Mayock et al.² emphasized that in 12% of a large series the age of onset was 50 years or later. While white males and

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, Minneapolis, July 12, 1966.

Continued

females appear to be affected about equally, negro females are affected with approximately twice the frequency of negro males.

Eskimos and Indians in Canada have little susceptibility to sarcoidosis in contrast to their high incidence of tuberculosis.³ The disease is rarely reported in the Chinese.

Etiology

Tubercle Bacillus

The specific cause of sarcoidosis has never been established. There is much dispute over the possible relationship to tuberculosis, and advocates of this etiology feel it is an aberrant form of tuberculosis: that the high incidence of negative tuberculosis reactions and the inability to isolate acid-fast bacilli from the lesions are due to an immunologic phenomenon such as a positive anergy.* More recently the suspicion cast upon the human tubercle bacillus is being shifted to the unclassified mycobacterium.³

Mankiewicz⁵ has postulated that certain lysogenic mutants of tubercle bacilli may be the causative agents; he has demonstrated that increased numbers of mycobacteriophages can be isolated from the stool, lymph nodes, and lungs of patients with sarcoidosis. When these phages act upon tubercle bacilli, lysogenic mutant forms can be produced. Sarcoid-like lesions can be produced in the guinea pig simultaneously infected with tubercle bacilli and mycobacteriophages.

Pine Pollens

Still more recently, the inhalation of various soil types and pine pollen have been suggested. Cummings et al.⁴ noted the close correlation between the birthplace of patients and the distribution of pine-forested areas. Their laboratory studies revealed pine pollen to have acid-fast characteristics similar to the tubercle bacillus, and when pine pollen was injected intradermally or subcutaneously in guinea pigs, a localized epithelioid cell granuloma was produced. This suggested a possible hypersensitivity to inhaled pine pollen as an etiology in some cases. Attempts to produce granulomas with pine pollen in patients with sarcoidosis have usually been unsuccessful.

Other investigators have related sarcoidosis to a variety of causes including viruses, mycotic infections, allergic or collagen-like diseases, syphilis and leprosy.

There are a number of organisms and physical agents which produce "sarcoid-like" granulomatous diseases. Among these are included a variety of fungi, lepra bacillus, zirconium, beryllium, pine pollen, specific soil types and certain hairsprays.

Pathology

Sarcoidosis is a protean disease characterized by the formation of non-caseating granulomas that may involve almost any organ or tissue of the body. The lymph nodes are most commonly involved, especially the hilar or tracheobronchial nodes, followed in frequency by the lungs, liver, spleen, skin, eyes and bones.

Histopathology

Microscopically the noncaseating granuloma is composed of large,

*See Test Your Word Score Page 221.

plump, closely packed, epithelioid cells surrounded by a scant rim of fibroblasts and a few scattered lymphocytes, with multinucleated giant cells interspersed throughout.⁶ Inclusion bodies have been described in the giant cells and are usually of two types: (1) asteroid bodies which are of yellow-brown granular structure with sharp ray-like filaments and may represent protein or metal deposits; (2) Schaumann bodies that resemble the corpora amylacea of the prostate.

Neither of these inclusions is pathognomonic, since similar ones are also found in beryllium lesions, nonspecific foreign body granulomas, early tuberculosis and certain fungal diseases. Caseation necrosis does not occur.

Coalescent Granulomas

The lesions may appear to be progressive, static or retrogressive. Coalescence of granulomas produces nodules of varying size visible macroscopically. In the lung, the lesions are distributed throughout the parenchyma, usually bilateral with some tendency to localize about blood vessels, bronchi and lymphatics. There is a tendency for the lesions to heal, leaving varying stages of fibrosis and hyalinization.

Although histopathology is extremely valuable in assisting in diagnosis, it is impossible to be unequivocal because of the inability to differentiate from Hodgkin's disease, lymphosarcoma, histoplasmosis and noncaseating tuberculosis, and other diseases in which noncaseating granulomas may be present. Thus pathologists can merely report the microscopic appearance to be compatible with sarcoidosis.

Clinical Features

The outstanding clinical feature of sarcoidosis is the disparity between the mildness of symptoms and the extensive involvement of the various organs. Sarcoidosis usually commences in an insidious manner; often attention is first drawn to the presence of the disease following a routine x-ray of the chest. As the disease progresses, symptoms invariably appear and usually consist of weight loss, fatigue and vague respiratory complaints including cough, breathlessness and chest discomfort.

Pulmonary

The frequency of systemic and respiratory symptoms in 160 patients with sarcoidosis are recorded in Table 1.⁷ As pulmonary function is

TABLE 1*
Frequency of Systemic and Respiratory Symptoms

Chest pain	29
Hemoptysis	7
No symptoms	11

*From Israel, H., M. Sones: Arch Intern Med 102:766, 1958.

Continued

compromised, dyspnea may reach major proportions with extensive involvement, productive cough and hemoptysis.

Hemoptysis in sarcoidosis is infrequent and massive pulmonary hemorrhage is rare. Its occurrence is attributed to concurrent pulmonary disease or a complication of sarcoidosis such as bronchiectasis. Massive fatal hemorrhage has been reported in six cases and is probably due to granulomatous invasion of the pulmonary vessels.⁸

Fever

Fever, if present, is usually low grade and occurs during periods of greatest activity of the disease. The mere presence of respiratory symptoms in pulmonary sarcoidosis signifies rather extensive involvement of the lungs.

There is usually a paucity of physical findings as compared to radiographic findings. Occasionally fine respiratory rales or scattered wheezes may be heard.

Pulmonary Involvement

The lungs are involved in approximately 90% of patients with sarcoidosis as evidenced on chest x-ray, and this would probably approach 100% if routine blind lung biopsies could be done on all cases. Even in the absence of symptoms or parenchymal abnormality on chest x-ray, almost all cases show impairment of pulmonary function indicating lung involvement.⁹ The type and degree of pulmonary involvement determines whether the patient will recover or be left with significant respiratory impairment.

Intrathoracic Stages

Siltzbach¹⁰ has classified the intrathoracic lesions by stages. *Early or Florid Stage*: a. Bilateral symmetric hilar node enlargement, usually asymptomatic and detected by routine chest x-ray. Disseminated pulmonary disease although not visible on x-ray may be shown by lung biopsy and decreased pulmonary function. b. Widely disseminated or localized fine miliary and occasionally gross miliary nodulation with hilar node regression or persistence. Patients with miliary lesions on the presenting chest film tend to have a poorer prognosis than those with only hilar node involvement. c. Diffuse bronchopneumonia infiltrations. *Transitional Stage*: Infiltration of the pulmonary interstitial tissue with granulomas and fibrous tissue causing a fine or coarse reticular appearance. Mild degrees of emphysema may be present. *Late or Fibrotic Stage*: Dense fibrosis and hyalinization of the granulomatous lesions occur. There is retraction of the lung roots with fibrous strands and nodules of varying sizes. Giant bullae and advanced emphysema may be superimposed.

Enlarged Hilar Nodes

Enlargement of the hilar nodes, usually bilateral, occurs in most cases of pulmonary sarcoidosis and varies from a slight increase to huge so-called "potato nodes." Although hilar adenopathy alone usually causes no symptoms of bronchial obstruction, mainly because of absence of inflammatory reaction around the nodes, an occasional case of airway obstruction has been reported. The bilateral hilar adenopathy syndrome occurs mainly in young adults, predominantly females, many of whom present with erythema nodosum accompanied by pain and swelling of the joints,

especially the ankles. In those without erythema nodosum, the joint pains are unusual.

Infiltration of the parenchyma of the lung produces a wide variety of both clinical and radiological pictures. Lesions are usually small and discrete but coalesce to form larger nodules widely scattered throughout the lungs, mimicking miliary tuberculosis but occasionally restricted to more localized areas. Extensive involvement may occasionally be seen in patients who are completely asymptomatic; and it is again stressed that there is little correlation between clinical findings and the roentgenologic appearance. The activity of sarcoidosis likewise cannot be determined on the basis of the x-ray appearance.

An unusual type of pulmonary disease is represented by large discrete nodules resembling metastatic carcinoma of the "cannon ball type" in combination with varying degrees of more typical pulmonary involvement.¹¹ Cullen and co-workers¹² report four cases presenting with diffuse pulmonary infiltrations manifesting primarily as airway obstruction. Pleural involvement is an uncommon finding in sarcoidosis.¹³

Abnormalities of Pulmonary Function

Previous studies have shown that the major abnormality in pulmonary function is reduction of the diffusion capacity. Less frequent defects have been reduced lung volume, reduced compliance, decrease in maximal breathing capacity and increased airway resistance.

Diffusion abnormalities are explained on the basis of perivascular and alveolar fibrosis, compliance defects by interstitial fibrosis, and air flow obstruction by peribronchial fibrosis.¹⁴ Alveolar capillary block may be evident in many advanced cases of sarcoidosis.¹⁵

Abnormalities of pulmonary function seem to bear no definite relationship to the degree of parenchymal involvement reflected by chest x-ray. As might be expected, extensive perivascular fibrosis and anoxia lead to the development of pulmonary hypertension and cor pulmonale.

Ting et al.¹⁶ studied the mechanics of breathing in 31 patients with extensive parenchymal lesions. They found that when the x-ray showed evidence of extensive fibrosis, then diffusion capacity, lung compliance and lung volume were impaired. When cystic or bullous changes were present, airway obstruction could be demonstrated by increased pulmonary resistance and a decrease in maximal mid-expiratory flow rate. Whereas restrictive changes and impaired gas exchange are the most frequently demonstrated pulmonary function abnormalities, small airways are frequently narrowed by peribronchial fibrosis. Reduction in compliance is associated with diminished vital capacity and is probably the major cause of dyspnea.¹⁶

Laboratory Data

Laboratory findings are neither pathognomonic nor consistent enough to afford great diagnostic value. Aberrations of serum proteins occur in about 50 to 70% with a "step-like" electrophoretic pattern, increases in α_2 , B, and γ globulin and an occasional decrease in albumin being frequently reported. Series including a predominance of Negroes show a higher frequency of hyperglobulinemia. It is interesting to note

Continued

that in a large series of 246 patients reported from a white European population, the electrophoretic pattern was abnormal in only 34%, with increase in γ and α_2 globulin being the most frequent, with only one patient showing a step-like rise in the globulin pattern.¹⁷

Eosinophilia of greater than 5% occurs in 20% to 30% of cases. The eosinophilia sedimentation rate is elevated in those with active disease, especially during febrile periods. Serum Ca. has been found to be elevated in 20% to 30% of cases and is not associated with osseous involvement. Elevated serum alkaline phosphatase and cephalin flocculation are frequently noted. Leukopenia is present in approximately 30% of cases, and occasionally thrombocytopenia is seen.

Skin Tests

Insensitivity to tuberculin testing is a major feature of sarcoidosis. Patients may react to tuberculin before the onset of sarcoidosis, fail to react during the course of the disease and regain tuberculin sensitivity on recovery. Some feel the depressed skin reactivity is due to an impaired immunologic mechanism caused by the systemic lesions. Others support the hypothesis that the inability to develop delayed hypersensitivity is a constitutional defect that is prerequisite to the development of sarcoidosis.¹⁸ British investigators have claimed that tuberculin sensitivity is not absent but merely suppressed in most cases and may be unmasked by the addition of cortisone to the tuberculin skin-testing material or the use of depot tuberculin.¹⁹

Bacillus Calmette-Guerin Vaccination

An extensive study by Sutherland et al.²⁰ in Great Britain, in which more than 54,000 young adults participated in a trial of tuberculosis vaccines, revealed that tuberculosis vaccination at age 14 neither protected against sarcoidosis *nor promoted this disease*, and the incidence of sarcoidosis in this population group was not influenced by the initial tuberculin status of the participant. Children in this series who failed to develop tuberculin sensitivity after two Bacillus Calmette-Guerin vaccinations, and were seemingly healthy were given Kveim tests, with a high proportion showing positive reactions.

Israel and Sones²¹ found that Bacillus Calmette-Guerin vaccination did not affect the Kveim reaction and that in patients recovered from sarcoidosis the vaccine could not induce tuberculin sensitivity.

Kveim in 1941 demonstrated that the intracutaneous injection of a saline suspension of sarcoid lymph node into a patient with sarcoidosis resulted in the development of a papule within one to four weeks. On biopsy its histology was that of the "sarcoid reaction." The Kveim reaction is positive in the vast majority of cases. The conflicting reports concerning its significance stem from the unpredictability of the antigen and from difficulty in its standardization.²² The Kveim test yields a variable number of false positives and may fail to detect from 20 to 25% of individuals with sarcoidosis. The incidence of positive reactions is greatest in early cases, decreasing with chronicity of the disease and becoming negative in a high percentage of inactive cases.

The recent report of successful transfer of Kveim reactivity to normal individuals by giving leukocytes from patients having sarcoidosis suggests

it may be an antigen-antibody reaction.²⁴ Limitations of the Kveim test are:

1. Scarcity of the antigen.
2. Difficulty in standardizing the material.
3. Occasional deterioration, which may eventually impair potency and specificity.

Biopsy

Diagnosis depends on anatomic pathological biopsy confirmation, a consistent clinical picture, and the exclusion of other diseases giving a similar picture.²³

Enlarged peripheral lymph nodes, cutaneous lesions, enlarged liver and spleen, lung and scalene fat pad are all excellent biopsy sources. Less commonly used sites are the gastrocnemius muscle, lacrimal glands, conjunctivae, tonsils and bronchial epithelium.

Mediastinoscopy has proved valuable in the diagnosis even when chest x-ray has not shown any widening of that region, and biopsy results from several series are most impressive (Table 2).²⁴ The bone marrow has not been of great diagnostic value, showing granulomas in less than 30% of cases.

TABLE 2*

*From Carlens, E.: *Ann Otol* 74:1102, 1965.

Course and Prognosis

The clinical course is quite unpredictable in the individual patient. In 25 to 50% of the patients, the disease runs its course over several years with eventual recovery. In another 20 to 35% some improvement occurs, but these patients are left with some functional impairment. Five to 15% tend to become worse with development of rather severe respiratory impairment. Five-year survival rates are quoted as 85 to 90% with most deaths due to pulmonary fibrosis, respiratory failure, pulmonary hypertension and cor pulmonale. Skin lesions of erythema nodosum, especially when associated with hilar adenopathy, tend to carry a good prognosis. Extrapulmonary manifestation, cutaneous and osseous lesions are associated with a poor prognosis.

Treatment

Recent attention has been focused almost entirely upon the use of corticotropin and corticosteroids. The active or proliferative stage of sarcoidosis shows the most dramatic response to these drugs. Systemic steroids are suppressive rather than curative, and initiation of treatment shortly after onset of the disease does not seem to prevent residua or

Continued

change in x-ray appearance. Lewis et al.¹⁵ reported that patients treated early with steroids had the mildest symptoms and functionally had diffusion abnormalities but not compliance or ventilatory defects. Steroids seem to suppress the granulomatous inflammation as well as the associated symptoms. Withdrawal of these drugs is followed by a recurrence of symptoms and worsening of the lung lesions, especially in the chronic case. Duration of therapy is variable and often a matter of trial and error, but in general, course of therapy should exceed two to three months. There are conflicting views on whether or not patients receiving steroids for sarcoidosis should be covered with antituberculous drugs.

Antimalarial drugs have also been used with reports of varying success.

Case Report

A 27-year-old negro female was admitted to Hennepin County General Hospital on May 10, 1966, complaining of shortness of breath of two weeks' duration. For ten days prior to admission she had noted intermittent pleuritic-type pain in the anterior mid-chest accompanied by a nonproductive cough and episodes of chilliness. She had been bothered by perennial attacks of wheezing and dyspnea since infancy. These attacks were usually precipitated by upper respiratory infections and were more frequent during the winter months. The patient had been diagnosed as having intrinsic bronchial asthma, and it is noted that all previous attacks had responded readily to the usual treatment, leaving the patient completely asymptomatic.

The patient had moved to Minnesota from Monmouth, Illinois, about ten years ago. She smokes one pack of cigarettes per day.

Physical examination revealed a well-developed, young negro female, in no apparent distress. Her oral temperature was 100 degrees F., blood pressure 90/60 mm. Hg., and pulse 108 per minute. Examination of the ears, nose and throat was negative, as was the fundusoscopic examination. Lacrimal and parotid glands were normal. There were bilateral enlarged anterior cervical nodes. Diminished breath sounds and fine rales were heard at the right base; later a pleural friction rub was audible over the right mid-lung field. Examination of the heart and abdomen was negative. No skin lesions were present.

Laboratory values: hemoglobin 12.6 gm. %, white blood count 8,000 with normal differential. Eosinophils were not increased. Erythrocyte sedimentation rate was 70 mm/hr. The urinalysis was negative. The serum calcium was 9.5 mgm. %, serum proteins 6.5 gm. % with albumin 3.8 gm. % and globulin 2.7 gm. %. Serum protein electrophoresis showed a borderline elevation in α and γ globulin and a decrease in the albumin fraction. BSP. retention was 8%, cephalin cholesterol flocculation negative and alkaline phosphatase normal. Mantoux skin tests were negative. Both skin tests and complement fixation tests with histoplasmin, coccidioidin and blastomycin were negative. Chest x-ray showed hilar node enlargement and bilateral pulmonary infiltrates involving the mid-lung fields. X-rays of the hands and feet were negative. An EKG. was within normal limits. Biopsy of the liver revealed multiple noncaseating granulomata. The Kveim intradermal skin test antigen was injected intradermally on 6/2/66; the resultant papule biopsies on 6/29/66 were read as positive. A right scalene node biopsy revealed numerous noncaseating granulomas compatible with sarcoidosis.

Pulmonary function studies revealed reduced maximal breathing capacity and total vital capacity with normal timed vital capacity consistent with mildly decreased compliance. Gas diffusing capacity was not determined.

Abstracts, Briefs and Commentaries

SURGICAL DISEASES OF THE CELIAC AND MESENTERIC ARTERIES

The author discusses the symptoms, signs and surgical treatment of occlusive processes of the celiac and mesenteric arteries. Etiology of the occlusive process includes atherosclerosis, emboli, trauma and congenital lesions as well as others.

In general, symptoms are characteristic — cramping postprandial abdominal pain, intermittent or constant, and made worse by large meals. There may be constipation early, later diarrhea. Weight loss is common. An abdominal bruit is often heard. A *lateral* aortogram is diagnostic.

The various surgical techniques to relieve the occlusive disease is well described. Special attention in the postoperative management is directed to (a) use of antibiotics, (b) the chronic malabsorption syndrome which slowly relents, and (3) the development of intestinal stricture secondary to the ischemia.

Comment: Abdominal angina is a treatable disease. A high index of physician suspicion is the key to the diagnosis.

Minneapolis, Minnesota

Rob, Charles: Surgical Diseases of the Celiac and Mesenteric Arteries. Arch Surg 93:21, 1966.

A NEW METHOD FOR DETECTION OF THE LEAKY GLOVE

In a rather intriguing manner the authors discuss their technique of discovering holes in surgical gloves — an electrical glove testing unit. The insulating effect of the surgical glove is negated as sterile saline contacts the skin of the surgeon, completing a circuit. A flashing light signifies the contact.

Two hundred and ten presterilized disposable gloves were tested preoperatively: 1.4% (3) were defective. Two hundred and thirty checks were performed during or after the procedure; 35% (80) gloves were defective.

The fingertips of the surgeons were plated on agar after the surgical scrub with commercial solutions and at the close of the procedure. Of

Continued

these 306 at each time, 161 plates had more, 63 had the same, and 82 had less bacterial growth postoperatively. Usually the bacteria was *S. epidermides*, and this was often found in postoperative wound infections.

Comment: Although not new, an ingenious detection unit that can be incorporated in every hospital.

Jerome T. Grismer, M.D.
Minneapolis, Minnesota

Russell, T. R., Roque, F. E., Miller, F. A.: A New Method for Detection of the Leaky Glove. *Arch Surg* 93:245, 1966.

SUCCESSFUL USE OF DEXTRAN IN PHLEGMASIA CERULEA DOLENS

The varied treatment of massive venous thrombosis, the serious nature of the disease and the post-treatment morbidity are briefly reviewed. The rationale for use of Dextran 75 is related to several factors: (a) adherence to the vessel intima as a negatively charged mononuclear layer, which increases the zeta potential and negative electrical charge on the formed blood elements, increasing repellency and decreasing sludging, (b) inclusion of Dextran into the red blood cell envelope, altering the abnormal reaction of disease and reducing the bonding action, (c) inhibition of clotting by insulation of the coagulation reactants from each other, and (d) other results of osmotic properties on blood volume, cardiac output, etc.

The author describes the type and indications for therapy with Dextran 40 and 75 in five patients. Prompt improvement in signs and symptoms was noted in each.

Comment: The discussion of this article is as important as the article. My own experience has been favorable. This, however, is not a general opinion.

Jerome T. Grismer, M.D.
Minneapolis, Minnesota

Levy, J. S., Tryspel, O. H., Bergen, J. J.: Successful Use of Dextran in Phlegmasia Cerulea Dolens. *Arch Surg* 93:33, 1966.

A NEW METHOD FOR DETECTION OF THE LEAKY GLOVE

Bacteria on the surgeon's hands cannot be totally obliterated by a scrubbing technique. The only barrier between the surgeon's hands and the wound is the intact surgical glove. The finger tips of surgical teams have been plated after a ten-minute scrub with antiseptic soaps. Plating was repeated after surgical operation following the removal of the gloves by a nurse. The plates were incubated for 48 hours and rated from grade 0 to 4. Grade 4 showed a growth of more than 30 colonies. Two hundred and ten standard, pre-sterilized, disposable gloves were tested immediately after the surgeon was gloved, and 1.4% were defective. A total of 80 defective gloves was found among 230 checks during or immediately after surgery (35%). Of 44 cases studied, 79 percent of either the surgeon or his assistants developed a defective glove before the operation terminated. In nine cases which lasted under one hour, five had a member of the team with a defective glove when the procedure terminated (55%). In 35 procedures lasting more than 60 minutes, 85 percent had a defective glove.

Cultures revealed the staphylococcus epidermidis as the most frequent bacterial growth but occasionally the hemolytic *S. aureus* was isolated. The authors, in a review of the literature, found the percentage of perforated gloves to vary from 10% to 30%.

The equipment used by the authors to detect perforated gloves while on the hands of the surgeon and assistants seems quite simple. The fact that the glove is nonconductive is the basis of the test. A sterile basin partially filled with salt solution is placed on the electronic stand, which is grounded to the conductive floor. The circuit is open. When the surgeon with conductive shoes places a hand with a defective glove in the basin the circuit is completed and a light flashes. A hole in the glove can be localized, even to which finger is defective.

One group in the United States and a second group in England had described equipment based on the same electrical principle.

The authors also state that because of their concern on the adequacy of scrubs, they had medical students scrub for 30 minutes with various antiseptic agents. They concluded that it was virtually impossible to remove all bacteria from the skin.

With their equipment close to the field of surgery, members of the team can test their gloves at intervals during operations.

COMMENT: I have no doubt that every surgeon has been concerned about holes in his gloves and those of his team. He is well aware of the fact that he cannot sterilize his hands either mechanically or chemically. By this method which seems quite simple and efficient, one source of infection, though not eliminated, could be detected early. Their surgical team tests their gloves for leaks frequently during surgery.

CARDIAC CATHETERIZATION

These individuals have succinctly described their objections to a recent editorial "Use and Abuse of Cardiac Catheterization" — J. L. Ankeney, Annals of Thoracic Surgery 5, 660, 1965. In their letter, these authors point out the need for accurate assessment of the cardiac problem not possible by conventional means. They also indicate that postoperative evaluation of surgical results is objectively served by cardiac catheterization. To summarize their letter — "The more completely the patient is studied, the better prepared is the surgeon to do his best with the most possible benefit occurring to the patient —".

COMMENT: The original editorial of J. L. Ankeney and the above correspondence deserve more attention. Cardiac catheterization can be performed with much greater safety than a cardiac operation or exploration. It is difficult for me to adopt the philosophy that complete study is not needed. One can only agree with Drs. Zimmerman and Demany.

PSYCHOSOMATIC PREDISPOSING FACTORS IN ALLERGIC DISORDERS

In this investigation, the authors examined 65 male college students, 41 of whom had been independently diagnosed as having allergies, and 24 of whom had been independently diagnosed as being free of allergies. Each student was examined for the presence of a somatic allergic predisposition by giving skin tests and a Histamine Challenge Test. Likewise, each student was examined for the presence of a psychological allergic predisposition by using a Parent-Child Questionnaire and a Family Interaction Test.

According to the authors' criteria, the allergic students had a greater somatic and a greater psychologic predisposition than the nonallergic students. Somatic factors indicating an allergic predisposition were found in 92% of the allergic and 33% of the non-allergic students. Psychologic factors indicating a psychological predisposition were found in 78% of the allergic and 50% of the non-allergic students. Both a psychological and a somatic predisposition were found in 75% of the allergic and in 25% of the non-allergic students.

On the basis of their findings the authors conclude that both somatic and psychologic factors are present in allergic illnesses. They speculate that the psychological factor of critical importance is a childhood experience of exaggerated dependency highlighted by maternal domination of the family. However, they also suggest that perhaps no specific psychological factor differentiates an allergic from a non-allergic patient.

COMMENT: This investigation confirms the sensitivity of allergic patients to histamine and to antigens. The evidence for a psychologic predisposition was not as strong. While a pathological degree of dependency may complicate or precipitate an allergic disorder, it is by no means proven that psychological factors cause these illnesses.

The Doctor's Workshop

Cardiopulmonary Resuscitation in the Community Hospital

ROBERT S. ELIOT, M.D., F.A.C.P.*

DAVID ROSEN, M.D.**

JEROME GRISMER, M.D.†

Minneapolis, Minnesota

THE VALUE OF an organized program in cardiopulmonary resuscitation is well established in large hospitals.^{1,2} Little attention, however, has been paid to the development of a workable program tailored to meet the specific needs of a community hospital. The employment of resuscitation measures by several lay and paramedical groups has already demonstrated a beneficial effect.^{3,4} Increasing public and medical interest now indicates the need for a plan of attack when cardiac arrest occurs in the community or in the community hospital.

It is recognized that a variety of illnesses are treated in a community hospital. The number of admissions for acute myocardial infarction may be small and inconsistent. A workable program then should be designed for not only acute myocardial infarction, but also for other illnesses requiring careful and continuous observation and treatment.

The purpose of this communication is to set forth an organized plan for cardiopulmonary resuscitation in the community hospital. The background for this has been developed from a study of the programs which now exist or are under development in certain community hospitals in Minnesota.

The problems of organization in a community hospital to handle cardiac arrest can conveniently be broken down into three areas: equipment, personnel, and a plan.

Equipment

Equipment has been over-emphasized. Too much attention has been paid to expensive electronic monitoring apparatus when, in fact, only simple and relatively inexpensive equipment is needed.

Of prime importance is equipment designed to secure and maintain an airway. Plastic oral airways and nasal catheters should be available. Laryngoscope and endotracheal tubes are required. Tracheotomy kits should be made up in advance. A hand resuscitator, such as the Ambu or PMR, is convenient. Adequate suction must be available. All of the above-mentioned can be found in any hospital.

The significant point is that an emergency cart must be organized in advance to include this and other equipment (Figure 1). It is obvious that cardiac emergencies arise not only in the intensive care units or the hospital wards, but may also happen anywhere within the confines of a modern hospital. An appropriate number of carts then can be strategically located throughout the hospital and moved to handle cardiac arrest whenever and wherever it occurs.

Electronic equipment should be kept to a minimum, but the defibrillator is necessary. Much controversy over AC versus DC defibrillation can be found in the literature, but there has been no documented superiority in the termination of ventricular fibrillation and, therefore, either type will do.^{2,5,6} The anterior-posterior paddles are preferred. A cardiac monitor is valuable in following a

†Mount Sinai Hospital, Minneapolis, Minnesota.

patient from moment to moment. For the purposes of a community hospital this should be a simple piece of equipment. Complicated pulse monitoring devices, automatic memory loops, and read-out devices are not necessary. The monitor should be one with which all the physicians and pertinent hospital nurses can easily become familiar. It should also be purchased from a company that can give adequate maintenance and repair.

It would perhaps be appropriate to comment on the relationship between a program in cardiopulmonary resuscitation and coronary care units. The value of coronary care units in reducing the mortality from acute myocardial infarction can no longer be questioned.^{7,8} The reduction occurs primarily in earlier detection and more rapid treatment of cardiac arrhythmias. However, regardless of the electronic sophistication of the units,

they are only as good as the personnel that staff them, and in turn their ability to handle cardiac arrest. The community hospital must handle all types of medical problems and in most instances cannot devote the space or personnel to develop a pure coronary care unit. Yet if one has (1) a good emergency cart, (2) a monitor and defibrillator and (3) medical and nursing personnel instructed in the technique of closed chest massage, the essential ingredients of a coronary care unit are all available within the framework of a more general intensive care unit.

It is also recognized that there are disadvantages in putting coronary patients into active and noisy intensive care units. Unfortunately, the alternative is usually to have no coronary care facility. Thus the intensive care unit becomes the better choice. Most of these units have a "quieter" area where one

Fig. 1 — (Left) Cardiopulmonary resuscitation cart demonstrating defibrillator, monitor, oxygen, suction apparatus, and medicine cart. (Right) Same cart as above demonstrating emergency drugs in opened drawer on cart. (Both photographs kindly submitted by Dr. Marcus Keil, Albert Lea, Minnesota).

or two beds can be designated as coronary care beds and continually monitored. In this way the hospital can utilize existing facilities and personnel to provide a service which fits the needs of the community. This approach appears more reasonable than taking a pre-packaged coronary care unit and cramming it into the existing facility.

Personnel

In this outline to be presented, the authors have adapted a plan which has worked well in a 250 bed hospital. The authors are presenting this as a guide only. Each hospital must view this from its particular vantage point.

Five Groups

There are five groups, each with a specific responsibility, which converge on the patient's bedside when the emergency signal is flashed.

The monitor — The defibrillator console is under the responsibility of the Central Supply (C.S.). The unit is stored in C.S., and repairs, etc., ordered through C.S. At the signal, this unit is brought immediately to the floor, an elevator key (on the unit) speeding the delivery.

Special drug cart — This is also under C.S. responsibility. Drugs and supplies are under constant inventory, especially after a "run." Thus the two main units are in one area for storage.

The anesthetist or anesthesiologist comes immediately with the necessary endotracheal airways and small anesthesia machine for ventilation. A ventilating unit should have a manual as well as an automatic control so as not to oppose manual cardiac massage.

Laboratory technician with an electrocardiograph. This same technician is available to return to the laboratory with blood samples, etc. This machine can be monitored by the nurse or physician if necessary.

Nursing Supervisor and one other nurse to carry out drug infusion, assist in massage, etc. These two (or better three) are most important to the physician who, if alone, must do the massage, insert an I.V. cut down (intra cath-medicut), etc. Nurse's aides or

orderlies can be trained in massage to assist the physician.

The Patient

In order of importance, the patient has: (a) an airway established, (b) cardiac massage, and (c) an intravenous route inserted to allow drug infusion. Once these three points have been accomplished, the patient is "under control" and the success or failure of the resuscitation will depend on many other variables.

Medical Plan

The Clinical Findings and Treatment in Cardiopulmonary Arrest

The patient who experiences cardiopulmonary arrest may be the victim of one of three major forms. The first is *cardiac standstill*; the second is a *ventricular arrhythmia*; and the third is *systemic collapse* or *shock*. Auscultation is frequently unrewarding since the patient with cardiac arrest or ventricular fibrillation may give no auscultatory evidence of cardiac action. Both the pulse and heart beat are often present, however, in the patient with peripheral circulatory collapse.

The presence of dilated pupils indicates that cardiopulmonary arrest has existed for more than a period of one and one-half minutes. Constriction of the pupils may indicate that the patient is either on drugs (such as morphine) or that cardiac arrest has occurred within a matter of 45 seconds. The following steps are useful in approaching the patient with suspected cardiopulmonary arrest.

STEP 1. The timetable following the loss of heart beat.

A. The loss of major pulses.

B. The loss of respiration (occurs 30 to 45 seconds following cardiac arrest).

C. Dilated pupils occur 45 seconds to 1½ minutes following cardiac arrest.

STEP 2. The institution of ventilatory resuscitation.

A. Mouth-to-mouth.

B. Mouth-to-nose.

C. Mouth-to-airway. (Endotracheal intu-

Continued

bation if possible, but do not delay until necessary equipment is available.

STEP 3. The institution of circulatory resuscitation.

A. External cardiac massage.

STEP 4. Identify the type of cardiac arrest by use of the electrocardiogram.

A. Asystole is indicated by the presence of a straight line on the electrocardiogram.

B. Ventricular fibrillation is indicated by a series of wiggly lines without a QRS complex.

C. Profound cardiovascular collapse is indicated by the presence of normal QRS configuration by the finding of decreased blood pressure and so forth.

STEP 5.

Involves a series of alternate treatment depending upon the type of cardiac arrest occurring.

ALTERNATE STEP 5. Treatment of asystole.

(The treatment of asystole includes complete heart block and severe sinus bradycardia since they present similar pathophysiologic states).

A. Percuss the chest.

B. Direct intracardiac injection of epinephrine (3 to 5 cc. of 1 to 10,000 solution).

C. Substitute isuprel (0.02 to 0.4 mg. every five minutes).

D. Substitute calcium chloride (3 to 10 cc. of 10 per cent solution every three to five minutes).

E. Always employ sodium bicarbonate (1 ampule every 5 minutes).

ALTERNATE STEP 5. The treatment of ventricular fibrillation.

A. Immediate A.C. or D.C. shock. Keep in mind the proper placement of electrodes. The use of the anterior-posterior electrode may be of considerable value here. One should employ an adequate amount of paste without unduly spreading it throughout the chest. Observe safety precautions, since incidental shock of the operator and assistants has occurred in several instances.

B. The use of I.V. procaine amide in 200 mg. increments or quinidine in 200 mg. increments should be instituted for refractory fibrillation.

C. If above methods fail, one might try 50 to 100 mg. of xylocaine intravenously with additional equal increments every five minutes to a maximum of 300 mg.

D. If defibrillation fails, D.C. counter-shock as well as the above measures may be attempted again. The operator should keep in mind that the anoxic myocardium cannot be defibrillated. Adequate oxygenation is tantamount to resuscitation.

E. Continue to use an ampule of sodium bicarbonate every five minutes.

ALTERNATE STEP 5. The treatment of profound cardiovascular collapse.

A. Employ the use of cardiotonic drugs, such as isuprel in the same doses as indicated for cardiac arrest.

B. Try vasopressor agents such as aramine or, in profound refractory collapse, levo-phed.

C. Use of large amounts of steroids up to 100 mg. of prednesone or 1 gr. of hydrocortisone.

D. Continue the use of sodium bicarbonate (1 ampule every five minutes) to prevent acidosis.

STEP 6. Post resuscitation treatment.

1. Constant electrocardiographic monitoring by use of an oscilloscope monitoring system.

2. Vital signs.

3. Assisted ventilation by intermittent positive pressure or artificial respiration if indicated.

4. Measurement of intake and output.

5. Maintenance of blood pressure capable of sustaining adequate urine output and consciousness.

6. Hypothermia if available has occasionally been shown to be of some value in this situation.

STEP 7. Recognition of complications of external cardiac massage.

It has been reported by several observers that rib fracture, cardiac contusion, laceration of the liver, severed blood vessels, bone marrow emboli, sternal fracture, laceration of the spleen, and the development of the flail chest can occur in patients treated by techniques of cardiac massage.^{4,9} These complications can be kept at an absolute mini-

mum if appropriate techniques are employed.

If the above methods are implemented, a survival of approximately 25 per cent of all in-hospital cases of cardiac arrest can be achieved.^{8,10,11} It should be recognized, however, that some patients will have residual neurologic and cardiovascular injury. Roughly 75 per cent of patients achieving cardiac resuscitation will leave the hospital in a satisfactory physiologic state.^{7,11}

Summary

This report presents a workable program for cardiopulmonary resuscitation in the community hospital. Included is an organizational outline covering personnel, equipment, and a plan of action. It is hoped that this approach will serve the interests of the community hospital which is charged with

the responsibility for care of patients with other serious illnesses as well as coronary artery disease.

Appendix

The basic emergency cart equipment includes:

- A. An airway
- B. Tracheotomy kit
- C. Hand Resuscitator (Ambu or PMR)
- D. Emergency drugs (as outlined in text)
- E. Oscilloscope and A.C. or D.C. cardioverter
- F. Suction apparatus

The authors will answer by mail or telephone any inquiries regarding specific problems by interested physicians and professional personnel. They also wish to express appreciation to the Minnesota Department of Health in deferring some of the travel expenses.

Special Article

Epidemiology of Accident Morbidity

Incidence and A Prevention Program

A. B. ROSENFELD, M.D.*
Minneapolis, Minnesota

A DEATH FROM an accident is as faithfully recorded as is a death from an infectious disease. A case of diphtheria is reported and the statistical data are widely used in the control of epidemics as well as providing a basis for preventive programs. Accidental non-fatal injuries, the chief cause of disability in the age group one to 34 years, are neither reported nor easily available. Thus, little definite epidemiological information exists for community control or prevention programs.

Estimates of the ratio of fatal to non-fatal injuries vary from 100 to 400.^{1,2} Yet most community accident prevention programs are based on mortality data, primarily because this is the only readily available information which can be utilized. Fatalities, however, are a poor index as to the actual extent and nature of accidents which occur over a given period of time within a specified population. Although accidents are the fourth leading cause of death in the general population, they are the leading cause of death in Minnesota of persons under age 35.³ The National Health Survey has shown that the toll from injury—in cost, hospitalization, and suffering—is even more staggering.² National data, however, are not always applicable to local problems. It was therefore decided to survey accidents in Brown County, Minnesota, as a cooperative effort of the State Department of Health and the County Medical Society.

Method

This survey is the first such general county-wide study of non-fatal accidents available in the state. The objectives of the study were to determine the number, type, and cause of medically-attended injuries, to orient community groups as to the nature of the

*Director, Division of Special Services, Minnesota Department of Health, Minneapolis, Minnesota 55440.

Continued

accident prevention problem and to develop effective means of preventing these accidental injuries and deaths. The survey was conducted by sending a checklist, the main items of which are listed in Table 1, to the 22 physicians in the Brown County Medical Society. They were asked to complete the checklist on all patients they examined who had had accidental injuries. The self-mailer checklist was sent to Dr. O. B. Fesenmaier, district health officer in Mankato, for review, and then forwarded to the State Health Department for tabulation and analysis. Two health educators periodically followed up the physician's report by a personal visit. This article covers the first eleven months of the study from October 1, 1962, to August 31, 1963.

Brown County

Brown County is a non-metropolitan area with a total population of 28,542 (1960 census). It contains one city of 11,114 (New Ulm), two towns of 3,492 and 2,701, and a rural population of 10,361. Twenty-two physicians serve the county; thirteen of

them practice in the city. All physicians cooperated in the survey to a greater or lesser extent. One physician filled out only one form; another completed 295 reports. City physicians submitted 87 per cent of all reports.

Reported vs. Expected Injuries

Physicians reported 1,423 injuries during the period of study. It does not appear that they recorded all injuries because of the variable number of cases reported by different physicians and because of low injury rate per capita when compared to the National Health Survey. If the injury rate in Brown County were comparable to the United States rate of 214 accidents per 1,000 persons, about 5,500 injuries should have occurred in the County. Table 2 shows a comparison of the number of reported injuries in Brown County to the number expected from the National Health Survey, varying from a low of 20 per cent in those 65 or older to a high of 34 per cent in the 15 to 24-year-old age group. Although the total reported injuries reached only 26 per cent of the number expected, we think that this first county survey of accidents in Minnesota is worth discussing.

Use of Data

The study was established to investigate how, why, where and to whom accidents occurred and to find means within the community to prevent accidents. After physicians sent in the checklist on patients, the results were summarized in a series of tables (Tables 3-8). The following discussion is based on the data in these tables and on information gathered during follow-up visits by public health educators.

How and Why Accidents Occurred

Knowing how and why accidents occur are the first steps towards prevention.⁴ Falls, cuts, blows, and collisions accounted for 911 or two thirds of 1423 accidents (Table 3). More than one fourth of all accidents resulted from falls, nearly one fifth from cuts, and over one tenth from blows. Only 8 per cent involved car passengers, pedestrians, or

ACCIDENT MORBIDITY — ROSENFIELD

cyclists. Physicians had difficulty judging why the accidents occurred and whether they were preventable. They indicated that 47 per cent could have been prevented and that 30 per cent were unavoidable; but in 33 per cent they could not determine the preventability (Table 4).

Where and to Whom

Table 5 summarizes where the accidents took place and what age groups were injured. More than half occurred to persons under the age of 25 years. Close to half of the accidents — 626 out of 1423 — took place in or around the home. Fifty-five per cent of the victims within the home were girls or women, while boys and men suffered 60% of the injuries outside the home. At

work ("Farm Occupational" and "Industrial place or premise"), males over 15 years old made up 83 per cent of all those injured. At play, males were also more susceptible to injury. Eighty-two per cent of persons injured at places of recreation were males, and 64 per cent were less than 25 years old.

Continued

Males also predominated in accidents on the street or highway (51 per cent), on sidewalks (58 per cent), and in school or on school grounds (77 per cent). Only in homes, in public buildings, and in the over-65 age group did women have more accidents. Over all, two thirds of those treated for injuries by physicians were males. Preschool children and students were the most susceptible to

injury (Table 6). Among adults, housewives and farmers were most often involved in accidents. Predictably, the safest occupations were those with the least physical activity — professional, managerial, sales, clerical and domestic.

Condition of Patient and Nature of Injury

Physicians reported nine fatalities. Seven males died, six of them over 25 years old (Table 8). Four patients — all males — were totally disabled. But over 92 per cent of the injuries were either non-disabling or only temporarily disabling. The most common types of injuries, in order of frequency, were lacerations and evulsions, which were responsible for almost half of the injuries, contusions and hematomas, strains or sprains, fractures, and burns (Table 7).

Preventive Program

After the data was analyzed, a community program was developed in cooperation with the New Ulm Junior Chamber of Commerce, teachers in the city and county schools, and farm agents and safety groups. The Jaycees started a "home hazard" hunt by giving elementary New Ulm school children a checklist of home safety hazards, the children

ACCIDENT MORBIDITY — ROSENFELD

completing the list with the help of their parents. The Jaycees' wives' organization conducted a course in baby sitting and child safety on Saturday mornings with the aid of local police, firemen, and a public health nurse. The Jaycees handed out a pamphlet, "When Teen-agers Babysit," to participants, taught safety techniques, and issued a certificate of completion to those who attended. Literature and a coloring book on poison prevention were distributed to elementary school teachers, to be given to their students for classroom use, along with other brochures on general safety, bicycling, and

swimming. Finally, a plan was worked out with the New Ulm Safety Council to establish a fire prevention program in the schools. This program, not yet in operation, will use fire prevention demonstration kits to illustrate the hazards of electrical, gasoline, gas and rubbish fires.

Summary

The Minnesota Department of Health conducted an eleven-month survey of physician-attended injuries in Brown County, Minnesota, the twenty-two physicians of that county supplying the data on a checklist.

Continued

They reported 1423 injuries: nine fatal, 1322 non-disabling or only temporarily disabling. Preschool children, students, housewives, and farmers comprised most of the injured persons, and the majority of their injuries occurred in or near the home. Using this information the members of the Department of Health worked with members of civic organizations, policemen, firemen, and teachers to organize accident prevention programs.

All the physicians participated to a greater or lesser extent. However, this method of gathering data is apparently inefficient as evidenced by the marked variation in individual physician reporting and total report-

ing of only one fourth of the expected number of accidents. Statisticians suggest that a proper sampling, surveyed for a limited time period, can provide more accurate information with less demand on the practicing physician's time and patience.

Acknowledgments

The medical survey was conducted by the District II Health Office in Mankato, O. B. Fesenmaier, M.D., health officer, and the section of public health education, Marie Ford, M.P.H., section chief. Jean Woodbury and Janet Garrison, public health educators, conducted the field work and follow-up. Robert Hiller, chief of section of vital statistics, provided the tabulation and evaluation of the survey. Jerry Sleeper, consultant on accident prevention in the section of maternal and child health, developed and supervised the educational program.

Wisdom Without Vanity

"Medicine," Dr. Tick had confided to flock after flock of students, "is a noble dream and at the same time the most ancient expression of error and idiocy known to man. Solving the mysteries of heaven has not given birth to as many abortive findings as has the quest into the mysteries of the human body. When you think of yourselves as scientists, I want you always to remember everything you learn from me will probably be regarded tomorrow as the naive confusions of a pack of medical aborigines. Despite all our toil and progress, the art of medicine still falls somewhere between trout casting and spook writing.

"There are two handicaps to the practice of medicine. The first is the eternal charlatanism of the patient who is full of fake diseases and phantom agonies. The second is the basic incompetence of the human mind, medical or otherwise, to observe without prejudice, acquire information without becoming too smug to use it intelligently, and most of all, to apply its wisdom without vanity."

— Ben Hecht: Miracle of the Fifteen Murderers.

Conclusion

After thirty years' practice, I am fully convinced that two-thirds of all my patients would have recovered without the use of physic, or the attendance of a physician. — Hufeland (1762-1836) German Physician

Northlands Regional Medical Program

Heart, Cancer and Stroke Law

Public Law 89-239

The Minnesota State Medical Association Foundation has been awarded a planning grant for \$370,904 for the year 1967. Comparable amounts are also made available for the year 1968 and the first half of 1969. The primary objective of the Northlands Regional Medical Program is to assist in providing the best possible medical care in the area of heart, cancer and stroke and related diseases for every resident of the region and thus to attempt to narrow the gap between the least satisfactory and the most satisfactory medical care available in the region. It is planned to accomplish these goals toward improving the overall health of the population without interfering with the pattern or methods of financing of patient care or professional practice or with the administration of hospitals. This will be accomplished with the cooperation of practicing physicians, medical center officials, hospital administrators, the department of health, and representatives from voluntary health agencies.

The following administrative arrangements for Northlands Regional Medical Program have been accomplished:

1. An advisory group has been organized to represent a broad spectrum of interests in the health fields and to represent the public. As the name of the program implies, areas adjacent to Minnesota may wish to be included in the planning. For this reason, representatives from Wisconsin, Iowa, and North Dakota have been included.

2. An executive committee has been formed as a working component of the local advisory group. This committee is made up of members from the two medical centers and from other health agencies in the state. Its members are:

Robert Barr, M.D.
Minnesota State Board of Health
Minneapolis, Minn.

Mr. Harold Brunn
Minnesota State Medical Association
St. Paul, Minn. Secretary Treasurer

Paul Ellwood, M.D.
American Rehabilitation Foundation
Minneapolis, Minn.

Ivan Frantz, M.D.
University of Minnesota
Minneapolis, Minn.

W. F. Mazzitello, M.D.
Minnesota Heart Association
St. Paul, Minn.

Mr. Jack Rivall
Minnesota Hospital Association
Minneapolis, Minn.

Donald Stewart, M.D.
Minnesota Cancer Society
Crookston, Minn.

J. M. Stickney, M.D.
Minnesota State Medical Association
Rochester, Minn.
Program Coordinator

J. P. Whisnant, M.D.
Mayo Clinic
Rochester, Minn.

3. Committees have been designated by the two medical centers to undertake institutional responsibility relating to the Northlands Regional Program.

4. Members of the medical staffs of the University of Minnesota Medical Center and the Mayo Clinic have held meetings with medical and hospital staff personnel at the community level in representative cities throughout the state of Minnesota, Western Wisconsin, and Northern Iowa. In these discussions, it was emphasized that local groups should assist in identifying individual needs with assistance from the regional planning group. As a result of these meetings, planning committees have been formed at the community level in many of the cities visited. These community planning groups will work

Continued

with the medical center staffs and the Regional Medical Program director's office.

5. Contacts have been made with adjoining regions to indicate that the Northlands Regional Medical Program is willing to cooperate in carrying out common programs in overlapping areas.

A number of studies will be undertaken in the early planning stages. The priorities and direction of these studies will be determined by the Northlands Regional Medical Program staff after consultation with the executive committee. Examples of studies are as follows:

1. Identify the resources and capabilities of educational and health service institutions in this region and establish their optimum role in the Regional Medical Program.

2. Determine present grant support and other support in the region for comprehensive health programs other than research project grants.

3. Integrate the efforts of existing medical care programs in regard to state and voluntary health agencies to reduce duplication and promote optimal use of facilities, personnel, and equipment for improved patient care.

4. Determine the existing patterns of patient referral and patient flow to physicians both in outlying regions and to the medical centers.

5. Determine the usefulness of part time educational directors at the community hospital level. Initial efforts will be made in a community and further efforts will be extended from that point.

6. Determine the location of medical and paramedical personnel related to the care of patients with heart disease, cancer, and stroke.

7. Determine the extent to which non-physician personnel could serve in patient care responsibilities and define the training necessary so that such an individual could undertake a role in patient care.

8. Determine the location of physical facilities and services that now exist and that may be necessary for proper diagnosis and treatment of heart disease, cancer, and stroke and consider the proper distribution of

special facilities and equipment in this region.

9. Study the clinical laboratory facilities available to provide diagnostic assistance in regard to heart disease, cancer, and stroke and determine whether regional laboratories would be desirable for special diagnostic tests or whether quality control procedures should be established for hospital or community laboratories.

10. Develop a procedure whereby the quality of medical care can be assessed at various levels of medical practice.

11. Explore more efficient approaches to diagnosis in heart disease, cancer, and stroke such as self-administered questionnaires for history taking and more reliance on routine laboratory procedures to conserve physician time.

12. Investigate the possibility of setting up uniform systems for patient data storage to permit instant retrieval and availability for research and educational purposes.

13. Encourage selected general physicians and internists in some communities to gain additional knowledge in diagnosis and management of either heart disease, cancer, or stroke by spending concentrated periods of time at one of the medical centers, so that such knowledge could be put to use in medical care at the community hospital level.

14. Encourage non-physician personnel to acquire special knowledge by spending concentrated periods of time at one of the medical centers, such knowledge to be put to use in special situations at the community hospital level.

Integration of efforts in continuing education by the medical centers will be an early goal of Northlands Regional Medical Program. The staff for planning and carrying out continuing education at the medical centers should be enlarged and the staff should explore new methods of enhancing continuing medical education. Consideration should be given to self-participation programs in the hospitals, self-teaching video devices, two-way radio communication, one-way telecasting, or two-way television teaching devices.

Identification of existing educational pro-

grams for medical and paramedical personnel that are now provided by voluntary and state health organizations will be necessary. The objectives of individual programs and the origin of the participants will be determined so that these programs can be integrated with other existing and planned programs.

The Northlands Regional Medical Program planning grant will provide funds for the following:

1. Discussions for planning among personnel from the two medical centers, the voluntary health agencies, the State Health Department, the State Hospital Association, the State Medical Association, and community planning groups.

2. Staff for the Northlands Regional Medical Program. Staff to include director and assistant, biostatistician, medical sociologist, research associates and assistants and administrative, secretarial, and clerical staff.

3. Office space for Northlands Regional Medical Program.

4. Support of time for University of Minnesota and Mayo Foundation personnel participating in program development and planning.

5. Clerical assistance for Medical Center planning personnel.

6. Support for medical or paramedical personnel from communities to obtain training in special areas or techniques at either medical center for short periods of time.

7. Support for three half-time area coordinators for education; these individuals to be responsible for assisting in planning continuing education for a community or area in cooperation with one or both medical centers.

Various pilot projects, feasibility studies or operational programs which arise will be evaluated by the executive committee and if approved will be presented to the regional advisory group for approval before submitting an operational grant request to the Division of Regional Medical Programs.

Any interested physician, hospital, or health agency is invited to correspond with the executive committee. Inquiry may be addressed to the Northlands Regional Medical Program, 496 Lowry Medical Arts Building, St. Paul, Minnesota, in care of Mr. Harold Brunn, the Secretary.

J. M. Stickney, M.D.
Program Coordinator

Importance of Direct Observation

There are several obstacles which have hitherto stood in the way of a more general adoption of the maxim that direct observation constitutes the best method of studying disease. They are the following: the widespread contempt for the authority of the physicians of antiquity; the false opinions and prejudices to which men became attached as if they were idols; the habit of making erroneous comparisons and of drawing hasty conclusions, as well as the formulating of analogies that are based upon untrustworthy reports; reading books which have been unwisely chosen or reading without exercising a discerning judgment; incorrect interpretation of the author's meaning; the craze for reducing everything to a system; and the abandonment, by authors, of the habit of expressing their thoughts in the form of maxims. — Giorgio Baglivi (1669-1707)

There isn't much coasting on the road to success. Success isn't in that direction.
— Williams Laboratory Review

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by
absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate signs of senile confusion. Patients become more alert,

aged and debilitated

ess confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, pathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 2 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

PHILIPS ROXANE LABORATORIES

Division of Philips Roxane, Inc., Columbus, Ohio

A Subsidiary of Philips Electronics and Pharmaceutical Industries Corp.

Geroniazol[®] TT

nicotinic acid 150 mg., pentylenetetrazol 300 mg.

Tempotrol[®] Time Controlled Tablet

Norinyl[®] tablets

(norethindrone 2 mg. $\bar{c}$ mestranol 0.1 mg.)

for multiple contraceptive action that has produced a record of unexcelled effectiveness

**inhibition of ovulation by means of
2 time-proved hormonal agents**

**production of a cervical mucus hostile to
sperm motility and vitality**

**creation of an endometrium unreceptive
to egg implantation**

no unplanned pregnancies

Norinyl provides multiple action for maximum assurance of success. It does not depend on ovulation inhibition alone for contraceptive effectiveness. The mechanism of action of combined hormonal therapy results in ovulation inhibition reinforced by other protective mechanisms, including a hostile cervical mucus¹⁻¹³ and an acceleration of endometrial changes.^{1-3,7-16} With Norinyl, no unplanned pregnancies have been reported to date when used as directed.

plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.

Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to con-

firm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-

ketosteroids and decrease in 17-hydroxy-corticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism. **Side Effects:** Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

norethindrone—an original steroid from
SYNTEX
LABORATORIES INC., PALO ALTO, CALIF.

Norinyl tablets
(norethindrone 2 mg. • mestranol 0.1 mg.)

for multiple contraceptive action

You can't set her free. But you can help her feel less anxious.

You know this woman.

She's anxious, tense, irritable. She's felt this way for months.

Beset by the seemingly insurmountable problems of raising a young family, and confined to the home most of the time, her symptoms reflect a sense of inadequacy and isolation. Your reassurance and guidance may have helped some, but not enough.

SERAX (oxazepam) cannot change her environment, of course. But it can help relieve anxiety, tension, agitation and irritability, thus strengthening her ability to cope with day-to-day problems. Eventually—as she regains confidence and composure—your counsel may be all the support she needs.

Indicated in anxiety, tension, agitation, irritability, and anxiety associated with depression.

May be used in a broad range of patients, generally with considerable dosage flexibility.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. One patient exhibiting drug dependency by taking a chronic overdose developed upon cessation questionable withdrawal symptoms. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose; excessive prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Safety for use in pregnancy has not been established.

Not indicated in children under 6 years; absolute dosage for 6 to 12 year-olds not established.

Side Effects: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age.

These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever, euphoria and dysmetria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam.

To help you relieve anxiety and tension

for that added measure of protection

SIGNE M

A 'MAXIMUM SECURITY' ANTIBIOTIC*

*** THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE**

long established as the broad-spectrum agent of first choice in a wide variety of infections

*** WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT**

triacytyleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline

*** ESPECIALLY VALUABLE IN U.R.I.**

provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered

*** NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY**

Signemycin 375 — high-potency capsules for simpler administration, greater patient economy

YCIIN[®] 375

(tetracycline HCl 250 mg.
triacytyleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacytyleandomycin*, a constituent of Signemycin, has been associated with deleterious changes in liver function. See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacytyleandomycin.

Precautions and Adverse Reactions: *Triacytyleandomycin*, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver

function are reversible after discontinuation of the drug.

Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacytyleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

GENERAL PRACTITIONER WANTED: To associate with physician-surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building 3 years old; with five large treatment rooms; lab.; x-ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85 bed City Hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D.; 920 South Cedar Street, Owatonna, Minnesota. Phone 451-4639.

PSYCHIATRIC RESIDENCIES July, 1967: Approved three-year progressive program in Metropolitan Detroit area. University associations. Teaching staff of board men, psychoanalysts, professors, outstanding visiting lecturers. Active research. Modern physical plant. Salary \$8,978;

\$9,405; \$10,213. Five-year career program \$10,232 to \$18,507. Liberal Civil Service benefits. General practitioners completed internship four years ago may be eligible for NIMH stipends of \$12,000 per year. Write, Director of Education and Research, Northville State Hospital, Northville, Michigan 48167.

GENERAL PRACTITIONER — to join established five-man group consisting of three general practitioners, a general surgeon, and an internist. Excellent clinic facilities situated adjacent to the city hospital. Starting salary negotiable. Retirement plan and many other fringe benefits. Call or write: Richard F. Lehigh, Owatonna Clinic, Owatonna, Minnesota 55060. Phone: 451-1120.

CLINIC BUILDING — In town on highway 12 in Long Lake. For sale or lease. Contact: Loren Monseth, Dahl Investment Co., Ta 7-1731.

WANTED — man to fill in two weeks in Feb. or March for general practice in the Twin City Area. Phone — 474-6228 Mpls. Salary open.

EXCELLENT OPPORTUNITY for Intern or Resident finishing in June or July to try practice in Specialty group on locum tenens basis — June 1 thru August 31, 1967. Replacing Internist on leave of absence. Option of remaining on staff if desired. Salary open. Write or call collect, 281-3184, Northwestern Clinic, Crookston, Minnesota.

GENERAL PRACTITIONER wanted by two-man general practice group. Surgery within capability. Community Hospital. Eligible partnership if preferred. Write: MINNESOTA MEDICINE — 393, 496 Lowry Medical Arts Building, St. Paul — 55102.

RESIDENTS IN PSYCHIATRY — Opening for July 1, 1967. Stipend \$11,400 for physicians just completing internship. Federal stipend of \$12,000 annually with an extra \$3600 tax exemption available to physicians with 4 years non-psychiatric training or experience following internship. Graduates of American schools must be eligible for Iowa licensure. Foreign graduates must have ECFMG certificate. This is an acute treatment city hospital. Starting salary negotiable. Retirement hospital with 450 (450) in-patients and large outpatient department, children's unit under direction of Board-certified Child Psychiatrist. Intensive didactic teaching program with rich clinical experience directed toward preparing the resident for Board certification. Thirteen senior staff members including ten Board certified. Numerous consultants authorized for 18 residents. Affiliation with University of Iowa. Enthusiastic training and treatment programs that are best appreciated by a personal visit. Write W. C. Brinegar, M.D., Superintendent or John J. Worthington, M.D., Director of Psychiatric Training, Mental Health Institute, Cherokee, Iowa 51012.

Too Opaque!

A prominent specialist in gastro-intestinal diseases once asked, "How is it possible that you, a general surgeon, see so many of these cases, while I, who am devoting all my time to this work, see so few?" I could only answer, "The thickness of the abdominal wall prevents you from seeing them." — William Mayo

Let's get
down to earth
about
diuretics

With Hygroton, you'll discover that you can almost always use fewer tablets than is possible with other diuretics.

You may be told that a new short-acting diuretic was found more effective than Hygroton in congestive heart failure—but this was when twice the manufacturer's maximum recommended dose was given.* At the maximum recommended dose for both diuretics, two tablets of Hygroton were far and away more effective than five tablets of the other diuretic in producing natruresis and weight loss. And at these dosages, Hygroton costs only $\frac{1}{3}$ as much as the other diuretic.

Since the discovery of chlorothiazide, the trend has been away from short-acting, multiple-dose, high-cost diuretics. With Hygroton you can usually do the job with just one tablet a day, or every other day.

More than any of the newer diuretics, Hygroton brings dosage and cost of medication down to earth.

*Brest, A. N., et al.: J. New Drugs 5:329, 1965.

Hygroton[®]
chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water. **Contraindications:** Hypersensitivity and most cases of severe renal or hepatic disease. **Warning:** With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind. **Precautions:** Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. **Side Effects:** Dizziness, weakness, nausea, vomiting, hyperglycemia, hyperuricemia, headache, muscle cramps, postural hypotension, constipation, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin reactions, including urticaria and purpura, epigastric pain, or G.I. symptoms after prolonged administration. **Average Dosage:** One tablet (100 mg.) with breakfast daily or every other day. **Availability:** Tablets of 100 mg. in bottles of 100 and 1000. For full details, see the complete prescribing information. 6524-V(B)

Geigy Pharmaceuticals
Division of Geigy Chemical Corporation, Ardsley, New York

Geigy

fluocinolone acetonide — an original steroid from

SYNTEX 
LABORATORIES INC., PALO ALTO, CALIF.

controls infected inflammatory dermatoses that start from scratch

The "itch-scratch" cycle usually associated with inflammation often results in infected dermatoses because broken skin surfaces are particularly vulnerable to pathogenic bacteria.¹ To treat infected inflammatory dermatoses, Neo-Synalar Cream combines the most active topical corticosteroid with a highly reliable antibiotic generally reserved for topical application.

In Neo-Synalar, fluocinoline acetonide controls the inflammation and provides rapid relief from associated pruritus. At the same time, its antibacterial component—neomycin—combats superficial infection caused by many gram-positive and gram-negative bacilli² that often colonize and thrive on abraded skin.¹

A specially formulated vanishing cream base that is greaseless and odor free makes Neo-Synalar cosmetically appealing, and encourages greater patient cooperation.

controls the infection

stops the scratch

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of its components. **Precautions:** Neomycin rarely produces allergic reactions. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. **Side Effects:** Side effects are not ordinarily encountered with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Neo-Synalar under certain conditions. **Availability:** Neo-Synalar Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

References: 1. Pillsbury, D. M., Shelley, W. B., and Kligman, A. M.: A manual of cutaneous medicine, Philadelphia, Saunders, 1961, p. 79. 2. Barber, M., and Garrod, L. P.: Antibiotic and chemotherapy, Baltimore, Williams and Wilkins, 1963, p. 111.

Neo-Synalar[®]

(fluocinolone acetonide-neomycin sulfate cream)

Cream

How long will it take him
to recover from the flu
if he just doesn't care?

Does he really care?
Is he alert, encouraged,
positive and optimistic
about getting out of bed
and back to work soon?

Or is he giving in to
the depressing impact
of confinement?

When functional fatigue
complicates convalescence,
Alertonic can help...

Pleasant-tasting Alertonic is pipradrol hydrochloride—an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that so often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

*Adequate dosage is important: Prescribe Alertonic—
one tablespoonful t.i.d., 30 minutes before
meals...tastes best chilled.*

*And for your patient's sake, prescribe Alertonic
in the convenient, economical one-pint bottle.*

Alertonic[®]

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B₁) (10 MDR*), 10 mg.; riboflavin (vitamin B₂) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B₆), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.

†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

special formula for a special problem

*specifically formulated
for symptomatic
relief of sinus headache*

Sinus headache is not a single entity,
but a chain reaction of pain.
It is facial pain—deep, dull, aching and
nonpulsating. It is referred pain—
originating in the nose and sinuses but
felt at another site. It may become
generalized pain and tension in head and
neck. It is one or all of these.

The Sinutab formula is designed
for symptomatic relief of sinus headache.

It provides two analgesics to relieve
pain and discomfort...an effective oral
decongestant to reduce mucosal congestion...
and an antihistamine to help
control allergic manifestations.

Side Effects: Epigastric distress, drowsi-
ness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive
or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid
disease, heart disease, hypertension, diabetes
or kidney disease. Excessive dosage or
prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

WARNER-CHILCOTT
Morris Plains, N.J.

SINUTAB[®] **for sinus headache**

Each tablet contains
150 mg. acetaminophen,
150 mg. phenacetin,
25 mg. phenylpropanolamine HCl,
and 22 mg. phenyltoloxamine
citrate.

B

TABLETS

Equagesic[®]

(meprobamate and
ethoheptazine citrate with
aspirin)

Precautions: Keep out of reach of children. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. Withdraw gradually after prolonged high dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance. If drowsiness, ataxia or visual disturbances occur, reduce dose. If symptoms persist, caution patients against operating machinery or driving. Give cautiously to patients with suicidal tendencies. Treat attempted suicide with immediate gastric lavage and appropriate supportive therapy.

Side Effects: Ethoheptazine and aspirin may occasionally cause nausea, vomiting, epigastric distress, and rarely dizziness and CNS depression. Overdosage may result in salicylate intoxication. Meprobamate rarely causes allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioedema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Rarely, cases of aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported; almost always, in the presence of known toxic agents.

Contraindications: History of sensitivity or severe intolerance to aspirin or meprobamate.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Wyeth Laboratories Philadelphia, Pa.

Weighing on his mind, too

When pain evokes anxiety and tension, thereby heightening patient discomfort, a simple analgesic may only touch on part of the problem.

This single-prescription, non-narcotic product, however, usually provides effective analgesia *and* helps put the patient's mind at ease.

Now, now, Mrs. Forsythe, we've never lost a cold patient yet.

When she's experiencing acute discomfort from cold symptoms, it's small wonder the patient becomes distressed about her condition.

She will breathe easier when you prescribe Novahistine LP.

Novahistine LP is a long-acting decongestant that helps restore normal mucus secretion and ciliary activity—physiologic mechanisms which prevent infection of the respiratory tract. A dose of two tablets taken in the morning and repeated in the evening will usually keep air passages clear for 24 hours.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution patients who operate machinery or motor vehicles that drowsiness may result.

Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

 **PITMAN-MOORE** Division of The Dow Chemical Company, Indianapolis

NOVAHISTINE[®] LP

For relief of nasal congestion.

Saxon

Minnesota Medicine at a Glance

Carcinoma of the Pancreas and the Ampulla of Vater — Sako Page 169

Early carcinoma of the pancreas is difficult to detect clinically. By the time the commonly recognized symptoms and findings occur, over three fourths of the patients have passed the stage where resection is possible. However, definite progress, though painfully slow, has been made over the past thirty years, as reflected in the continued decline in operative mortality, and also in a five-year-survival rate as high as 14% at the hands of some operators with extensive experience in surgery of the pancreas.

Management of Head Injuries — Wilson and Norrell Page 177

Most patients with acute head injuries can be successfully treated at the average general hospital without neurosurgical consultation. Close observation of the patient is essential. A baseline in the patient's general condition and neurological signs must be established and all changes promptly noted. Except for extradural hemorrhage, head injuries usually do not constitute surgical emergency; and other serious injuries may take precedence. Head injury alone rarely produces shock. In the comatose patient tracheostomy is necessary to maintain a free airway, and nasogastric suction to prevent aspiration. A urinary catheter will elicit genitourinary injury and also aid in assaying fluid balance by monitoring the patient's output. Bradycardia, a rise in systolic blood pressure, and slowing of the respiratory rate signify increased intracranial pressure and require immediate consultation. Extradural hemorrhage requires emergency evacuation of the hematoma and may have to be done by any surgeon available without special equipment. A technique is presented.

Retrograde Arteriography — Sweet and Grismer Page 185

Sweet and Grismer have found the percutaneous non-catheter retrograde brachial arteriography to be entirely safe and reliable for the purpose of demonstrating the abnormalities in the vertebral vessels. They have used it in 55 studies with no adverse effects. The details of the technique are well described in their manuscript.

Addiction — Koutsky and Larson Page 189

Addiction to drugs and alcohol was the major problem in 7.5 per cent of the patients admitted to a general hospital psychiatric service. Minor tranquilizers and non-barbiturate sedatives are of major importance in the problem. Addiction is easily overlooked in patients with better social adjustment or in those with medical or surgical complaints. Addiction occurs in people of all social classes whether of rural or metropolitan origin. Seventy-four per cent of these patients showed significant problems with depression or character disorders. Deaths have been reported following the withdrawal of barbiturates, meprobamate, and methypylon. Grand-mal convulsions, hyperpyrexia, and delirium are symptoms of impending disaster. The authors discuss the effects of abrupt withdrawal versus gradual withdrawal of these medications and recommend the grad-

ual withdrawal of the drug of addiction to avoid complications. Although their data is too limited to make a definite statement, they suggest the use of anti-convulsants during withdrawal. They feel that phenothiazine drugs are safe to use during withdrawal provided anticonvulsant treatment is given concomitantly. They urge further study of the effectiveness of anti-seizure medication during withdrawal. They comment on the serious difficulty in achieving satisfactory follow-up care for the chronic addict.

Wringer Injuries — Garrick

Page 195

With the advent of the automatic clothes washing machine, wringer injuries are now seen much less frequently by physicians. Nonetheless, their severity should not be underestimated. The extent of damage to crushed tissues cannot be accurately assayed at the original examination. The physician who initially examines and treats the injury should not make the error of undertreatment just because there are minimal superficial signs of injury. The first treatment should consist of a gentle, thorough, aseptic cleansing of the involved extremity, suture of lacerations, followed by a carefully applied massive compression dressing. Tetanus prophylaxis should be given. Further treatment depends on the condition of the tissues at subsequent dressings in the next few days.

Gastrointestinal Bleeding Caused by Aortojejunal Fistulization — Larson et al.

Page 203

Aortoenteric fistula is a surgical emergency which must be suspected in any patient with gastrointestinal bleeding who has had a previous abdominal aortic graft. The faulty graft must be exposed and completely removed at the time of reconstruction. This complication can be prevented at the primary procedure by meticulous construction of the aortic anastomoses, avoidance of a discrepancy in the size of the host aorta and the graft, avoidance of injury to the bowel wall, and interposition of viable tissue between the graft and the bowel.

Hereditary Hemorrhagic Telangiectasia — DeSanto

Page 233

Telangiectasia of the skin with hemorrhage, often nose bleed, and a history of hemorrhage in the family represent the triad known as Rendu-Osler-Weber disease. Many methods of treatment have been tried and many complications from treatment have resulted. Therapy should involve the least drastic procedure necessary to control the symptoms. Iron replacement and transfusions, often many transfusions, are necessary.

Intuition

Perhaps the ability not only to acquire the confidence of the patient, but to deserve it, to see what the patient desires and needs, comes through the sixth sense we call intuition, which in turn comes from wide experience and deep sympathy for and devotion to the patient, giving to the possessor remarkable ability to achieve results. — William Mayo

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test¹⁻¹⁰ Reed¹¹ in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

When the stagnant sinus must be drained...

Transillumination of the sinuses — diffuse shadow on right side of face indicates unilateral maxillary sinusitis.

In the common cold, Neo-Synephrine is unsurpassed for reducing nasal turgesence. It stops the stuffy feeling at once. It opens sinus ostia to re-establish drainage and lessen the chance of sinusitis. With Neo-Synephrine, in the concentrations most commonly used, decongestion lasts long enough for extended breathing comfort, without endangering delicate respiratory tissue. Systemic side effects are virtually unknown. There is little rebound tendency.

Neo-Synephrine[®] HCl

Brand of phenylephrine hydrochloride

is available in a variety of forms,
for all ages:

- 1/8% solution for infants
- 1/4% solution for children and adults
- 1/4% pediatric nasal spray for children
- 1/2% solution for adults
- 1/2% nasal spray for adults
- 1/2% jelly for children and adults
- 1% solution for adults (resistant cases)

Also NTZ[®] Solution or Spray
Antihistamine-decongestant

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Picture of low back pain

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

President's Letter

IF THE SOCIAL planners have their way and — make no mistake — they are a powerful and effective group in this country, we have acquired an illuminating glimpse into some of their ideas at a recent hearing before the Minnesota State Legislature House Committee on Appropriations. Mr. Fitzsimmons, as well as the other members of his committee who were present, may not have liked what they heard any better than I did.

We heard testimony from many people that day regarding "Medical Manpower." One of the principal physicians to give testimony was Osler L. Peterson, M.D., of Harvard University, Executive Director of the "Health Manpower for the Upper Midwest" study, requested by the University of Minnesota Board of Regents, and financed by the Louis W. and Maud Hill Family Foundation of St. Paul. This report is well worth study by each physician in our Midwest and North Central area.

In this letter I shall comment on one small, but important part of his testimony. He stated that "transportation will have to take the place of specific services." With this we can all agree. With the dwindling supply of physicians in rural America, Dr. Peterson urged that we should consider doing what most of the European countries have done, namely, make much more use of paramedical personnel for as many services as possible, in order to free the physician for more technical work. Among those suggested was an almost vanished person, at least in this area, the "midwife."

Dr. Peterson asked (to paraphrase him): "If England, as well as other European countries can use their services, why not

America?" I would like to pose this question: Just because these other countries use midwives to replace physicians in the prenatal, natal, and postnatal periods, does this mean that this is good? In my opinion this step would be retrogressive. Unfortunately, "it could happen here." All who have studied the subject agree that it will take many years before enough physicians are graduated to meet the needs. These studies show that, if expansion could start immediately, it would still be at least 1975 before more physicians could be made available.

We would hope that an adequate number of these future physicians and, indeed, of our presently graduating young men and women, might choose to begin to fill the vacancies in rural areas. We don't want this done by legislation, but that could happen too.

An equally urgent, and even more disturbing problem, in this writer's opinion, is the need for redefinition of the term "General Practitioner." The search goes on, and will be the subject of a future letter.

With the rapidly expanding population, plus stepped-up research in all fields, diabetes continues to tantalize the best judgment which any physician can offer to his own group of patients with this disease. This issue is devoted especially to newer thoughts on this important subject, and we recommend it for your study.

Diabetes Mellitus

Outline of Methods for Early Diagnosis

GEORGE D. MOLNAR, M.D.*
VAHAB FATOURECHI, M.D.**
FREDERICK J. SERVICE, M.D.**
Rochester, Minnesota

SYMPTOMATIC DIABETES mellitus is usually easy to diagnose. Clinically latent, earlier stages of diabetes are not. Application of recently acquired knowledge in this field permits ever earlier diagnosis, if the proper tests are correctly applied. A brief survey of this vast and fast-growing segment of the literature on diabetes is the purpose of this communication.

Diabetes mellitus can be defined as the abnormal metabolic state related to deficient insulin activity. This deficiency refers not only to the level of circulating insulin, which may actually be low, normal, or high,¹ but also to the effectiveness of endogenous insulin, which in turn is customarily gauged by tests of glucose tolerance. However, impaired carbohydrate metabolism is not necessarily synonymous with diabetes, since a host of conditions such as myocardial infarction, severe burns, blood dyscrasias,² and some endocrine disorders may also impair carbohydrate tolerance. Although carbohydrate metabolism is certainly *not all* that is disturbed in diabetes, traditionally, when doubt exists, tests of glucose tolerance are still the standards whereby diagnostic decisions are reached.

Screening Tests

Screening tests for diabetes (Table 1) include urinalysis and fasting or postprandial blood-sugar determination. The urine specimen examined can be a single voiding or a prolonged collection. The analysis can be qualitative or quantitative³ and specific for glucose³ or simply a measurement of reducing substances. The subject can be in the fasting or postprandial state. The load of carbohydrate, if one is administered, can be measured or unmeasured. The individual may be free from or

**Mayo Graduate School of Medicine (University of Minnesota), Rochester: Residents in Medicine.

under spontaneous or deliberate stress in terms of the absence or presence of illness other than diabetes or through the administration of adrenocortical steroids. Obviously, all of the foregoing considerations affect the relative diagnostic value of urinalysis as a screening procedure for diabetes.

For blood tests used in screening for diabetes (Table 1), the specimen can be venous or capillary or arterial, whole blood or plasma, and the analysis can be specific for glucose or not, and performed manually or by automation.⁴ More important, how-

ever, is specifically whether the subject is in the fasting or postprandial state.

Fasting Blood Sugar

When the fasting concentration of blood glucose is significantly increased, repeatedly and under acceptable conditions, the diagnosis may be made and tests of tolerance omitted. Obtaining a fasting specimen has the advantage of being easily standardized, as it is easy to instruct a patient not to eat after the evening meal the night before the test. For the early detection of diabetes, however, the fasting blood-glucose measurement is insensitive.⁵

Postprandial Blood Sugar

A postprandial specimen for blood-glucose determination with a timed sampling procedure after a measured load can be useful for early diabetes detection, but a randomly collected specimen following an unmeasured load has been shown to be just as inefficient as the fasting blood-glucose determination for the same purpose.⁶ About 30% of very early cases will be missed.⁶ If a measured load is used, its magnitude can be of considerable importance.

As will be mentioned later with reference to tolerance tests, the subject's preparation for an isolated blood test is also of importance.

Tolerance Tests

The considerable variety of tolerance tests, in all of which changes in blood-glucose concentration are measured, is indicated in Table 2.

Oral Tolerance Test

Among oral tolerance tests, food or glucose can be the load. Doses of carbohydrate given range between 50 and 100 gm. The glucose load, if one is calculated, ranges from 0.5 to 3 gm./kg. of body weight; but this may also be calculated on the basis of kilograms to the 0.7 power⁷ or be suitably adjusted to body surface area. Furthermore, actual or ideal weight or surface area may be used in such calculations (Table 2). The duration of the test is two to five hours

and the sampling can proceed half-hourly, hourly, or on a continuous automatic recording basis.⁴

Intravenous Tolerance Test

The intravenously administered load of glucose can be given rapidly, that is, usually in about three to five minutes, or slowly throughout an hour. The loads range from 0.25 to 3 gm/kg.,⁷ and again the various considerations cited previously for body size may be taken into account. The usual dose is 25 to 50 gm., the duration of the test is one to three hours, and sampling can be done every 15 or 30 minutes or continuously.

Cortisone-Glucose Tolerance Test

Further refinements of load tolerance testing involve varieties of the cortisone-glucose tolerance test. This now is the prototype of a test designed to detect an earlier stage of diabetes.⁸ The glucose load is administered during the effect of a previously given adrenal corticosteroid. A good indication for the use of cortisone-glucose tolerance tests is in kinship surveys of diabetic patients to diagnose prediabetes.^{8,9}

Insulin-Glucose Tolerance Test

The insulin-glucose tolerance test involves the administration of insulin in conjunction with a load of glucose. Indications for this test are suspected impairment of either insulin responsiveness or carbohydrate tolerance or of both. Impairment of insulin responsiveness seems to be an important phase in the pathogenesis of diabetes.¹⁰

Tolbutamide Tolerance Test

The tolbutamide tolerance test measures insulin secretory capacity of the pancreatic islets. It differs from the other tolerance tests by employing a noncarbohydrate load. Even more intensive stimulation of insulin secretion may be obtained through combined administration of glucagon, tolbutamide, and glucose.¹¹

Preparation and General Condition of Subject

An important aspect of all the tests is

preparation of the subject. If the test is done on an unprepared subject, carbohydrate intolerance may be observed because of starvation in a normal individual, perhaps through the mechanism of enhanced secretion of growth hormone.¹² In a mildly diabetic subject, abstinence from carbohydrate consumption or starvation may ameliorate the tolerance test to the point of a normal response through improved ability to secrete insulin.¹³ Dietary preparation also helps to standardize a test so that repetitions may yield essentially similar responses.

The Influence of Calories

Wilkerson and associates¹⁴ have shown that, with a calorically adequate diet, carbohydrates might be restricted to less than 50 gm/day before abnormalities show up, but even they recommend dietary preparation with 150 to 200 gm. of carbohydrate for at least three days.¹⁴ Others recommend a level of 300 gm.¹⁴ With an average North American diet, fat and protein content of the dietary preparation need not be especially emphasized, though generally it is important. Thus the matter of the total calories consumed prior to the test is important, and even eating habits matter: nibbling of food favors and gorging impairs carbohydrate tolerance.¹⁵

Influence of Exercise and Drugs

Lack of exercise prior to the test, such as confinement to bed for some time, may impair carbohydrate tolerance, whereas exercise during the test improves it, especially in the mild diabetic.¹⁶ Supine position delays gastric emptying and alters glucose absorption.¹⁷ The oral glucose tolerance test is best done with the patient in the sitting position. Drugs being used by the patient such as corticosteroids,¹⁸ sex steroids¹⁹ (oral contraceptives),²⁰ and thiazides are known to affect carbohydrate tolerance. The patient must be questioned in this regard.

Influence of Age and Disease

Age and state of health are other factors to be considered (Table 3). It is increasingly

well documented that age from childhood through adolescence to old age brings with it progressive impairment of carbohydrate tolerance.²¹ It may be justifiable to adjust diagnostic criteria for diabetes according to age.²¹ Pregnancy, endocrine diseases, other diseases, and major stresses may have adverse effects on carbohydrate tolerance. In general, it is justifiable to make a working diagnosis of diabetes in the presence of another illness, but it is important that re-testing be undertaken when the patient is fully treated or cured.

Diagnostic Criteria

The diagnostic criteria depend on a laboratory's normal range. Decisions based on a single abnormal point are unjustified. In the oral glucose tolerance test the two-hour value may nevertheless be the most impor-

tant single value. A value of 110 mg./100 ml. by a so-called true blood-sugar method is considered abnormal.²² The one-hour value may be the next most important; values above 150 mg. may be abnormal. When available, the 30- and 90-minute values can help resolve an otherwise borderline result. The fasting value should not exceed the normal range for the particular laboratory. The three-hour value likewise should be back to the normal (fasting) range, and if hypoglycemia is present, this, too, can be of diagnostic significance. Ninety minutes after an intravenous load of glucose, values in the normal fasting range are expected. Calculations of a K-value, or rate of glucose utilization, the slope of glucose disappearance, and the glucose-disposal rate have advantages in yielding a single number to describe the organism's response to the glucose load.⁷

Additional Diagnostic Methods

Measurement of substances other than glucose (Table 4) during a glucose tolerance test provides means of detecting diabetes especially in early, prediabetic, or borderline conditions.

Plasma Insulin

Important recent progress has provided radioimmunoassay and bioassay methods for determining plasma insulin. Normal fasting values for plasma insulin vary with the method of determination. After an oral glucose load, peak values for insulin are reached in 30 to 60 minutes. These are usually three to 10 times the fasting value^{1,23,24} and return to fasting level in 120 minutes.²³ During the intravenous glucose tolerance test, the plasma-insulin response is significantly lower and less sustained.²⁵

In mild maturity-onset diabetes a delayed but exaggerated insulin secretory response to glucose loading may occur.¹ In contrast, very low or no insulinogenic reserve is the rule in juvenile-onset diabetes.¹

Serum Free Fatty Acids

Other parameters listed in Table 4 can be measured during tolerance tests. How-

ever, a number of these at present have limited application and as diagnostic aids are still controversial. For instance, in a diabetes survey, although fasting free fatty acid levels in the group with impaired but not fully abnormal carbohydrate tolerance were elevated in 30%, there was also a wide scatter of values in normal subjects.²⁴ Elevated fasting levels of free fatty acids are a frequent finding in diabetes, and indeed elevated free fatty acid levels have been incriminated in the impairment of glucose tolerance.^{26,27} Shafrir and Gutman's response curves obtained during oral glucose tolerance tests showed that 50% of those suspected of having diabetes had distinctly abnormal free fatty acid values similar to those obtained from diabetics.²⁸ However, the finding that 40% of the non-insulin-dependent proven diabetics gave normal free fatty acid responses raises serious doubts about the diagnostic usefulness of this parameter. Abnormal free fatty acid-response curves have also been observed²⁹ during rapid intravenous glucose tolerance tests in subjects genetically predisposed to diabetes, in contrast to normal responses in normal subjects.

In relatives of diabetic patients, in whom blood-glucose and free fatty acid values were normal during oral glucose tolerance tests, the cortisone-glucose tolerance test yielded borderline glucose values and also distinctly abnormal free fatty acid response curves during the latter test.³⁰ These data support the thesis that free fatty acid measurements may disclose the first detectable abnormalities in individuals genetically predisposed to diabetes.²⁹

Hypertriglyceridemia

Impaired carbohydrate tolerance has been recognized in hypertriglyceridemia by use of oral and intravenous glucose tolerance tests measuring glucose and free fatty acids.³¹ The usefulness of determining fasting triglyceride levels as an aid to diagnosis in early or borderline cases, however, is hampered by the fact that 30 to 40% of the normal population have some degree of hypertriglyceridemia.

Microangiopathy

When biochemical changes in body fluids are still normal or borderline, light and electron microscopic studies of tissue biopsy specimens from renal and other tissues for microangiopathy and from skin for elastic-tissue changes, and in-vivo observations on the microcirculation of the bulbar conjunctiva show great promise³² for early detection of diabetes. This approach has the advantage of independence from biochemical diagnostic methods.

Summary

Methods of diagnosing diabetes mellitus have been outlined with emphasis on detection of early phases of the disease. In borderline cases, tests of glucose tolerance alone or in combination with biochemical determination other than blood-glucose measurement or in combination with tissue diagnostic methods will often, but not invariably, resolve the diagnostic dilemma. The importance of proper preparation of the subject and consideration of his general condition when he is being tested for diabetes must not be neglected.

IT'S THE LAW

Live Birth Defined

1. Statutory Provision

"Live Birth" means the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy, which, after such separation, breathes or shows any other evidence of life such as beating of the heart, pulsation of the umbilical cord or definite movement of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached; each product of such a birth is considered live born. (Section 144.151, Minnesota Statutes Annotated through 1964 Supplement)

Fetal Death Defined

1. Statutory Provision

"Fetal death" or "stillbirth" shall have such meaning, in terms of the duration of pregnancy, as the State Board of Health may from time to time by regulation ascribe to such words. (Section 144.151, Minnesota Statutes Annotated through 1964 Supplement)

2. Regulation

Fetal death is death prior to the complete expulsion or extraction from its mother of a product of conception after twenty weeks of gestation. The death is indicated by the fact that after such separation the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles. (Regulation 126, Minnesota State Board of Health, effective March 9, 1956)

When Fetal Death Registration Is Required

From the definition set forth above, fetal death registration is required if the 20th week of gestation has been completed.

1. Statutory Provision

A certificate of every . . . stillbirth shall be filed . . . within five days . . . with the local registrar. (Section 144.163, Minnesota Statutes Annotated through 1964 Supplement)

Medical Men on Postage Stamps*

Charles Nicolle (1866-1936), Nobel Prize winner in 1928, was a French physician who did valuable research in rinderpest,** measles, diphtheria, scarlet fever, tuberculosis, and Malta fever and who helped to distinguish between louse-borne and murine typhus. His chief distinction lies in his being credited with the discovery that typhus fever is transmitted by the body louse. His contributions to medicine were given recognition by Tunisia on a postage stamp issued in 1952 and by France in 1958.

Armauer Hansen (1841-1912) was a Norwegian physician who discovered the leprosy bacillus. A postage stamp in his honor and in celebration of the International Leprosy Congress at Havana (1948) was issued by Cuba in 1948. Also Brazil in 1948 and Belgium in 1964 commemorated Hansen's contribution to medicine.

Insulin Preparations

Their Actions

WILLIAM R. KIRTLEY, M.D.*
Indianapolis, Indiana

A DECADE has passed since the advent of oral therapy for the treatment of diabetes mellitus. The first such preparation, a sulfonylurea, was designated Carbutamide, or BZ-55, the numerical portion of the title indicating the approximate year of beginning interest.¹

In ten or more years a new therapeutic approach for an important disease can be fairly completely explored, to the point where the subject has little appeal to the medical writer, or, for that matter, to the medical reader. While there still remain a number of extremely important scientific truths to be spelled out regarding the mode of action of the sulfonylureas, the clinical application of these agents has become much a matter of routine and these drugs are, in the minds of many, the first therapeutic tools to be used once the diagnosis of maturity-onset, nonketotic diabetes has been made. It can even be said that on occasion the sulfonylureas may be employed in place of diet therapy, rather than ancillary to this more basic consideration.

Diabetic patients have remained the same. It is only that we now catalogue them differently and a different attitude prevails. Where previously the feeling was that in case of doubt use insulin, the current, perhaps unvoiced, opinion is expressed as: when all else fails, use insulin!

Assuming, however, that the decision has been reached that insulin is to be employed, what logical sequence can be followed to establish the best possible control for the particular patient?

Without becoming embroiled in a precise definition of what constitutes the best possible control, let us agree that the closest approach to continuous normoglycemia, without the production of inadvertent hypoglycemic episodes, will be the goal that is sought.

*Lilly Research Laboratories.

Diet Is Still Essential

In any attempt at diabetic control, the preliminary steps have remained unaltered. Insulin requirements can be determined with a fair degree of accuracy only when dietary regulation has been simultaneously, or in some cases previously, established. Quite commonly the diabetic is overweight, but even if he is not it is easier to bring about good management if, initially at least, a restriction is placed on total caloric intake.² Once an insulin response is obtained, it is fairly easy to increase the diet in a stepwise fashion until intake equals requirement, related to sex, age, body build, and occupation.

Choice of Insulin for Initial Therapy

Depending upon the severity of the diabetes encountered and the rapidity with which control needs to be established, a choice will be made between soluble, rapidly acting regular insulin and one of the modifications. At this initial point it is impossible to judge the type of response that may be obtained, and in the absence of acidosis (*mild* ketosis not presenting quite the

same degree of urgency) it is acceptable to use a longer-acting insulin.

Intermediately-Timed Insulins

Experience has shown that either Lente insulin³ or NPH insulin,⁴ so-called intermediately timed insulins, will be effective in some 80 to 85 percent of insulin-requiring diabetics. Therefore, it is reasonable to start with one of these modifications and to adjust dosage depending upon response. Such diabetics can be adequately controlled as outpatients⁵ once they are taught a method of urine testing and of course given diet instruction. Also, it is essential that they understand insulin administration, so that they may follow telephone instructions on dosage adjustment, if required.

It is of great help to the physician to have available a blood-sugar value fasting which can serve as a rough guide for the first dose of insulin. If the blood sugar is under 200 mg. percent, 10 units would be an acceptable initial dose; if over 200 mg. percent, then probably 20 units would be more suitable.

Urine-sugar values should be recorded by the patient four or five times daily, and daily adjustment in insulin can be ordered. If urine tests are persistently 3 or 4+, the basic dose can be increased four or five units each day until the glycosuria clears, or at least does not exceed 2+.

A precautionary note may be helpful. As urine sugars begin clearing it is frequently necessary to question patients closely regarding the occurrence of symptoms of hypoglycemia, since they may assume that hunger and nervousness are natural correlaries of restricted food intake. Actually, a judicious cutback in insulin dosage may be indicated before really serious hypoglycemia becomes manifest.

Usually, six to ten days will be required to establish the routine insulin dosage. Once this is accomplished, a stepwise increase in food intake can be initiated, if desirable. From a base line of 1200 calories per day, increments of 300 to 400 calories can be added, and not uncommonly these increases are possible without a need for insulin adjustment, a certain degree of tolerance to

Fig. 1 — Types of response to a single daily dose of NPH insulin.

carbohydrate being regained during the normalization of the blood sugar by the use of insulin. A final maintenance dietary level of 1800 to 2500 calories should be the goal.

Regular Insulin as the First Choice

A patient may exhibit symptoms requiring a somewhat more rigorous approach to control, and especially so if ketosis is apt to progress into acidosis. In these circumstances regular insulin needs to be considered of first importance, since it is imperative to reverse the ketotic process as rapidly as is compatible with safety.

Using the previously described method of fractional urine testing, regular insulin is given on a scale of 4 or 5 units for each plus value, before meals and again at bedtime, if necessary. Obviously it is desirable to transfer the patient to modified insulin as soon as possible. This can be initiated on the second day of therapy by taking approximately one half to three fourths of the total insulin dose of regular insulin and converting to Lente or NPH insulin. This amount is given in the morning before breakfast, and again supplements of regular insulin are given on the following day. Subsequent increases in the basic dose of modified insulin will depend upon the amount of supplemental regular insulin required.

For these relatively stable diabetics, the routine is fairly easy to establish. Since perhaps 80 percent of the insulin-dependent group fall in this category, these measures should be given first consideration. The real problems lie in the remaining 20 percent. These patients have the typical juvenile, labile diabetes and frequently require customizing of the insulin regime. Here one can use to good advantage the other modifications of insulin, such as Semi- and Ultralente, and various mixtures or multiple-dose technics.

There can be no set rules. Only general principles can be outlined, and an understanding of the scope and limitations of each type of insulin must be in hand.

Actions of Insulin Modifications

Insulin preparations are classified according to their time activity, which is a con-

venient method for comparing one modification with another. However, it must be realized that this specific action cannot hold for all diabetics and that patient variations in response to any single preparation will be encountered.

Normal Reaction

In the average patient, regular insulin reaches a peak of activity in thirty minutes to one hour and has a duration of five to seven hours. Individual patients, however, may react in patterns that are entirely different. An extreme example, and admittedly a rather rare one, is the patient who gets along quite well on a single dose of regular insulin given in the morning before breakfast, requires no further supplemental insulin, and yet without this single dose exhibits hyperglycemia and glycosuria throughout the day.

Variation in patient response is probably more commonly encountered when the modified insulins are used. As an example, Lente and NPH insulins have similar effects. On an average, onset occurs in an hour or two and peaks in four or more hours, with a duration of approximately 28 to 30 hours; yet, as is frequently seen, responses on both sides of this norm are encountered.⁶

Short Reaction

In some patients the action is far too short in duration and concurrently the onset is too rapid. This response will be reflected in the clinical findings of low blood-sugar values during the late morning and early afternoon, with a rising sugar in the evening, or at least over the sleeping hours, accompanied by nocturnal glycosuria (Figure 1-a).

Prolonged Reaction

Quite the reverse situation can also be seen. In some there will be a lag in onset, with a prolongation of hypoglycemic effect, so that mid-day hyperglycemia will occur in the face of low or normal fasting sugar levels (Figure 1-c).

These responses have been graphically represented by Hallas-Møller⁷ and described

as the "A" curve, "B" curve, and "C" curve, in which the "B" curve is the normal desirable response (Figure 1-b).

Correction of Distorted Blood Sugar Curves

It can be readily seen that if one attempts to control either situation by merely increasing the dose of Lente or NPH, the distorted curve will be reinforced and the threat of deeper hypoglycemia will become manifest. Only a change of emphasis will remedy the situation. In the first instance, it would seem that an insulin with longer action would be helpful, as indeed it is in some cases. This would be the type of patient response in which Ultralente in combination with the basic Lente dosage, or more rarely alone, would have a desirable effect. Since Ultralente and Lente are chemically identical, mixtures can be prepared at will without any concern for the ratio of the mixture.

Twice Daily Administration

It should be kept in mind, however, that not all patients will achieve good control with one daily dose of any insulin or combination of insulins, and in these individuals two doses of the intermediate (Lente) insulin may be required.⁵ Usually, two doses, the first consisting of 60 to 80 percent of the total daily dose requirement, given before breakfast, and the remainder before the evening meal, will resolve much of the difficulty.

Should NPH insulin be used, one cannot as easily prolong its action, since Protamine zinc insulin or Ultralente should not be mixed with the NPH. Therefore, the split-dose technic is the approach that is recommended.

Mixture of Insulins

When a more rapid effect is desired, Lente insulin is subject to two approaches. Mixtures of Semilente insulin (whose activity is only slightly more prolonged than that of regular insulin) and Lente can be made in any desired ratio, since again the two preparations have identical chemical properties. Mixtures of regular insulin and Lente insulin do carry some restrictions, but only

insofar as the ratio of the two is concerned. It has been determined that extemporaneous mixtures in which the ratio of regular to Lente is 1:1 or less are chemically compatible. Higher ratios can theoretically be less stable, since the pH of such a mixture will be lowered to a point where the insulin-zinc complex of the Lente becomes unstable and the prolonged action is lost.

Shortening the action of NPH insulin can be easily accomplished by the addition of regular. The NPH crystal is relatively stable; therefore, mixtures can be made with no concern for ratios.

The choice of insulin for the specific diabetic patient is a matter of fitting the action of the particular insulin or insulins to the type of diabetes encountered. Fortunately, most diabetics will respond to a satisfactory degree and in a sense "any insulin is good insulin," as was voiced by Dr. E. P. Joslin many years ago. Because of differences in response, there can be a place for Protamine Zinc insulin and Globin insulin, but as an indication of the over-all accepted use in the United States 55 percent of the total units of insulin used is in the form of NPH insulin, 20 percent as Lente insulin, 15 percent as Protamine Zinc insulin, and the remainder as regular, Globin, and the less generally applicable modifications, Semilente and Ultralente. Since Lente insulin and NPH have identical "timing," it is evident that the intermediate action is by far the most useful.

Insulin Allergy

On occasion, special situations will arise requiring the selection of insulin on a basis not necessarily related to timing of insulin release. Local sensitivity characterized by the appearance of redness, itching, and induration at the site of injection can occur early in the initiation of therapy. Fortunately, most such occurrences are self-limited and after a week or so the local reaction disappears and gives no further trouble. Antihistamines can be given orally with good effect in many cases, and on occasion mixing an injectable antihistamine with the insulin just prior to administration has been reported to be beneficial.

Experience has shown that in some cases the selection of insulin based upon the animal source and the use of pure beef or pure pork insulin can terminate local reactions, with more satisfactory response usually resulting from the use of beef-source insulin.

Single-species insulins are available. All modifications can be had made from beef pancreas and all except Semi- and Ultra-lente made from pork pancreas.

Insulin Resistance

A second type of response which can at times be improved by using single-species insulin is insulin resistance.^{8,9} Here the situation is reversed. Pork insulin has been shown to be more effective, presumably due to the fact that it more closely resembles human insulin in its amino-acid structure. Insulin binding or inactivation can be caused by specific antibodies, and such binding is seemingly less frequent with pork-source insulin in individual patients. Therefore, it is worth considering the use of pork insulin when high insulin dosage is encountered not due to dietary indiscretions.

Experimental Insulins in Resistance

Desalinated Pork Insulin

To effect an even closer resemblance of pork insulin to human insulin, it has been possible to remove a single variant in the amino-acid sequence of pork insulin, so that the remainder is identical to human insulin. Alanine is the variant and, being the terminal amino acid in the "B" chain of insulin, can be removed by enzymatic action without significantly altering the biological activity of the insulin. The use of this altered insulin can, in some cases, result in an added increment of dosage reduction. This specially treated insulin has been designated desalinated pork insulin, which for convenience has been shortened to Dalanated pork insulin.^{8,9} It is as yet only experimentally available.

Sulfated Insulin

A second preparation in the same state of

experimental use is so-called Sulfated insulin.¹⁰ In this instance insulin is treated with sulfuric acid in such a way that a certain amount of denaturation occurs and presumably is no longer recognized as an antigen by the insulin-binding antibodies. Although the experience is small, marked reduction in insulin dosage has been reported in some severely resistant patients. Sulfated insulin is not available in the United States and currently can be obtained only in Canada.

Other New Developments

Two new modifications of insulin have been available on a limited basis, but as yet proof of definite improvement in the control of diabetes is not available. These preparations, known as Actrapid and Rapitard insulin,¹¹ differ from the Lente modifications only in the fact that the total zinc content is reduced to approximately one tenth.

Much of a sensational nature has appeared in the literature concerning synthetic insulin, particularly in reference to the recent report coming from China indicating that total synthesis has been effected.¹² This is indeed a fact but should be regarded as only one step in a long series of experiments which have been conducted in a number of research centers, both in the United States^{13,14} and in Europe,¹⁵ as well as in China. The likelihood of the availability of clinical supplies of synthetic insulin in the near future is quite remote. These reports of progress of synthesis are important in their own right and may be quite helpful to scientists in devising tools to assist in a better understanding of the action of insulin and other metabolic processes.

Summary

Insulin therapy still remains the keystone in definitive therapy of diabetes mellitus. The severe, acute complications of the disease, ketosis, acidosis, and coma, can be treated only with insulin. The use of insulin in the routine management of diabetes continues to increase year by year, and the principles of management have remained unchanged. A review of the practical considerations of such management is presented.

Aphorisms of Maimonides (1135-1204)

Part I

1. Man is bound to lead a life pleasing to God if he wants to have a healthy body, and he must hold himself far from everything that can hurt his health and accustom himself to whatever renews his strength.

2. A man must not overload his stomach but be content always with something less than is necessary to make him feel quite satisfied. He should not drink much during the meal and only of water and wine mixed, taking somewhat more after digestion has begun and after digestion is completed, in moderation according to his needs.

3. Food should be taken always in the sitting position. There should be no riding nor walking, nor movements of the body until digestion is finished. The man who takes a walk or any strenuous occupation immediately after eating subjects himself to serious dangers of disease.

4. Day and night should be divided into twenty-four hours. Men should sleep for eight hours, and so arrange their sleep that the end of it comes with the dawn, so that from the beginning of sleep until sunrise there should be an eight-hour interval.

5. During sleep a man should lie neither on his face nor on his back but on his side, the beginning of the night on his left and at the end on his right. He should not go to sleep for three or four hours after eating and should not sleep during the day.

6. Fruits that are laxative, as grapes, figs, melons, gourds, should be taken only before meal time and not mixed with other food.

7. Eat what is easily digestible before what is difficult of digestion. The flesh of birds before beef and the flesh of calves before that of cows and steers.

8. In summer eat cooling food, acids, and no spices. In winter, on the contrary, eat warming foods, rich in spices, mustard, and other heating substances. In cold and warm climates one should eat according to the climatic conditions.

9. There are certain harmful foods that should be avoided. Large salt fish, old cheese, old pickled meat, young new wine, evil-smelling and bitter foods are often poisonous. There are also some which are less harmful, but are not to be recommended as ordinary nutritive materials. Large fish, cheese, milk more than twenty-four hours after milking, the flesh of old oxen, beans, peas, unleavened bread, sauerkraut, onions, radishes and the like. These are to be taken only in small quantities and only in the winter time and they should be avoided in the summer. Beans and lentils are to be recommended neither in winter nor summer.

10. As a rule one should avoid the eating of tree fruits, or not eat much of them, especially when they are dry and even less when they are green.

11. The fruits that are to be recommended dry as well as fresh, are figs, grapes and almonds.

12. Honey and wine are not good for children, though they are beneficial for older people, especially in winter. In summer one-third less of them should be eaten than in winter.

The Regulation of Insulin Secretion

FREDERICK C. GOETZ, M.D.
Minneapolis, Minnesota

INSULIN IS IN many ways the best known of all hormones, and yet mystery and controversy continue to be associated with many aspects of its role in the economy of the human being. There is no disagreement, however, concerning the importance of insulin in body metabolism. Regulation of insulin secretion from the pancreatic islet seemed not long ago to be a relatively straight-forward and well-understood matter; now, however, in the light of recent information, it appears likely that it is a far more complex problem than had been realized.

There is at present considerable disagreement concerning the role of insulin deficiency or of inadequate insulin secretion in the common form of diabetes (the stable "adult" variety) and in the beginning stages of juvenile diabetes. Even if some degree of insulin deficiency proves not to be the first event in the development of human diabetes, it seems highly likely that disordered insulin secretion plays a major role in the established metabolic disturbance.

It is curious that sulfonylurea drugs, such as tolbutamide, now widely used in the treatment of diabetes, are capable of increasing secretion of insulin from the pancreatic beta cells even though the elevated blood glucose concentration in these subjects is no longer able to provoke a normal response. While it may be that increased insulin secretion is not the entire explanation for the hypoglycemic effect of these drugs, their action on the beta cell clearly points to the possibility that blood glucose concentration may not be the sole determinant of insulin secretion.

It is the purpose of this brief review to point out the fascinating variety of recent information which indicates that other factors than blood glucose may play an important part in insulin regulation. Attention will be restricted primarily to physiological

substances. For a detailed bibliography, the interested reader is directed to references given below.^{1,2}

Glucose and Insulin Secretion

Direct Effects of Glucose

When insulin was identified as a hormone, it was natural to assume that its secretion would be regulated in some manner by glucose, the substance most obviously associated with the action of insulin in the body. Indirect evidence that insulin secretion could be provoked by glucose was furnished by animal experiments in which local injection of glucose into the arteries supplying the pancreas — especially a transplanted pancreas — led promptly to a *drop* in blood glucose in the general circulation of the experimental animal.

However, it was not until the recent advent of sensitive and specific assays for insulin itself in blood that direct confirmation of insulin release following glucose administration was obtained. By now an overwhelming number of studies have made it clear that in human beings and in many other animals administration of glucose by several different routes leads to a prompt and striking increase in insulin concentra-

tion in pancreatic venous as well as systemic blood.³

It is also very natural to infer from such experiments that it is the glucose molecule itself, reaching the pancreatic beta cell, which in some manner excites secretion of insulin directly at its source. Strictly speaking, however, such evidence is not furnished by experiments in intact human subjects or intact animals, in which glucose clearly reaches all other tissues in the body as well as the beta cells. Ideally, the beta cell should be studied apart from any other cell or tissue; to my knowledge no such study has as yet been successfully performed. The closest approaches so far have been to isolate the rat pancreas and to perfuse it *in vitro* (albeit with a portion of gut and spleen attached) (Grodsky and others) or to study slices of the whole rabbit pancreas *in vitro*.⁴ Such studies do indeed show a prompt outpouring of insulin on exposing the preparation to increased glucose concentration. Grodsky has shown that the response is very swift, occurring in about 30 seconds after the increase in glucose, and also shutting itself off just as quickly when glucose concentration has fallen back to baseline levels.

It is worth noting that it has not been

LIVER- β CELL CYCLE (PROPOSED)

Fig. 1 — A diagram illustrating the idea that metabolism of carbohydrate in the liver may set off an early signal to the beta cell to release insulin, before any rise in the concentration of glucose bathing the beta cell has occurred. The location of such a carbohydrate-responsive receptor in the liver is hypothetical.

possible to determine the minimum sensitivity of the beta cell to glucose — the smallest rise in blood glucose which will set off increased insulin secretion. Such information, if secured in an isolated pancreas preparation, might not be relevant to what goes on in the intact human or animal. Furthermore, the possibility that there may be interaction between the different kinds of cells in the pancreatic islet, or between the cells of the digestive portion of the pancreas and those of the islet, has in no sense been ruled out by the available studies. The following discussion will indicate that such interaction is no longer merely an academic possibility.

Insulin Secretion after Glucose, Not Mediated by Blood Glucose Level

While there appears no reason to doubt the direct effect of blood glucose on the pancreatic islet — and probably the beta cell — at least two kinds of evidence have appeared in recent years to suggest that the action of glucose may not be solely restricted to such a direct effect. Several studies have compared the effect on blood insulin levels of glucose given by mouth vs. glucose given into a peripheral vein; the experiments of Elrick and others⁵ are typical. Blood insulin levels were strikingly higher in normal human subjects following glucose given by mouth, in comparison with levels after identical doses of glucose given by vein; blood sugar levels were if anything lower after the oral glucose despite the higher insulin response. This finding has lead to renewed interest in the possibility expressed many years ago that some substance or factor located in the gut itself might act as an insulin-releasing substance. In our own laboratory, using a wholly different approach, we have found that injection of small quantities of glucose into the portal vein — well beyond the pancreas, of course, — lead promptly to insulin release from the pancreas, even though no increase in blood glucose concentration is observed. This led to the suggestion that arrival of glucose in some tissue other than the pancreas — and perhaps in the liver itself — could set off some sort of a rapid signal

to the beta cells to begin insulin secretion, even before blood glucose had risen (see Figure 1).

These suggestions are not necessarily mutually exclusive. They have lead to some further interesting developments which will be described below.

Substances Other Than Glucose Which Lead to Insulin Release

Other Carbohydrates

The natural six carbon sugar *mannose* shares with glucose the ability to stimulate directly increased insulin output from the beta cell. This effect has been shown in the isolated animal pancreas, but mannose is also capable of inducing insulin secretion in the human being. Whatever the direct effect of glucose on the beta cell may be, the response to mannose suggests that it may not be a completely specific one.

It appears from studies of intraportal in-

Fig. 2 — Summary of 10 experiments in normal anesthetized dogs showing the marked increase in pancreatic vein insulin output during intraportal infusion of ribose. Note that blood glucose concentration is slowly falling at the same time.*

*From Goetz, Maney and Greenberg: J Lab Clin Med, in press.

infusions of various sugars into dogs⁶ that two other natural sugars, galactose (six carbons) and ribose (five carbons) share the ability to evoke insulin secretion even though arterial glucose concentration is not raised or even if it falls. The effect of ribose is especially striking (see Figure 2). Subsequently we have observed prompt rises in peripheral blood insulin concentrations after giving ribose in normal unanesthetized dogs and in normal humans as well, despite the drop in blood glucose which has previously been known to follow ribose administration. Both ribose and galactose have been found to be ineffective in provoking insulin secretion in the isolated animal pancreas. Thus the possibility suggests itself that the metabolism of these sugars somewhere in the body — liver or elsewhere — leads to the rapid appearance of a "second messenger" of some kind which promptly increases pancreatic insulin output.

While neither of these two sugars is an important food constituent by itself, they can both be metabolized by normal mammalian tissues, share major metabolic pathways with glucose, and therefore suggest the possibility that they may share with glucose certain basic pathways for the regulation of insulin secretion.

Amino Acids

For many years a diet rich in protein has been considered to be the appropriate treatment for reactive or functional hypoglycemia in the adult subject. Recent findings on the effect of amino acids on insulin secretion are therefore something of a shock. Fajans and his collaborators have been especially active in investigating this area⁷. Their work stemmed from the observation that the amino-acid leucine promptly provokes hypoglycemia and insulin release not only in cases of the severe idiopathic hypoglycemia of infancy, but also in many adult subjects harboring an insulin-secreting islet cell tumor of the pancreas. It is now clear that leucine induces release of insulin and a modest drop in blood sugar even in normal subjects, but also that this effect is greatly exaggerated by pretreatment of the same

subjects with the sulfonylurea drug chlorpropamide (Diabinese[®]). Furthermore, a meal rich in protein produces elevations of plasma insulin levels considerably greater than those to be expected from the leucine content of the whole protein. Further study of a mixture of ten essential amino acids has shown that a number of these beside leucine are capable of inducing insulin release, and of these arginine is the most effective. The effectiveness of arginine, however, is not enhanced by prior treatment of the subject with chlorpropamide. Thus the mechanism of action may be somewhat different from that of leucine.

Fajans and his group suggest, from their *in-vivo* studies, that the amino acids themselves, and not their metabolites, may be directly affecting the pancreatic beta cells to cause insulin release. This matter is of course subject to further investigation in isolated pancreas preparations.

Ketone Bodies and Fatty Acids

Kipnis and others have shown that intravenous infusions of fatty acids into normal subjects are followed by elevation of blood insulin levels. This effect may not represent direct stimulation of the beta cell; however, according to the concept of the glucose-fatty acid cycle promulgated by Randle and others, elevated levels of nonesterified fatty acids in the blood may impair the ability of body tissues to respond to insulin, thus leading to a rising blood glucose concentration and a secondary stimulus to release of insulin. Also, beta-hydroxybutyric acid and acetoacetate have been reported to stimulate insulin release in anesthetized dogs. However, neither fatty acids themselves nor these products of fatty acid metabolism have been shown to stimulate insulin release directly *in vitro*.

Hormones, Including Glucagon

As has been noted above, several studies have indicated that glucose given by mouth is more effective than glucose by vein in provoking insulin release. This observation has led to an explosion of renewed interest in the possibility that the intestine may be

involved in the normal process of insulin release, by way of some mechanism triggered by the arrival of glucose in the intestinal lumen. There are at least three possible candidates for a hormonal intermediate in such a mechanism: glucagon, secretin, and pancreaticozymmin.

The possible role of glucagon may seem especially surprising at first glance, since it might be thought that the purpose of this substance in the body is to elevate the level of blood sugar by way of its well-known effect on increasing glycogen breakdown in the liver. However, it now appears that blood glucagon levels rise after the oral administration of glucose (but not after the intravenous administration); it also has been shown unequivocally that pancreatic glucagon is capable of exciting prompt insulin release from the isolated pancreas, where there is no simultaneous change in perfusing glucose concentration. It is possible that the intestine itself may contain glucagon or glucagon-like polypeptide which could be involved in the insulin release mechanism.

Further, while secretin and pancreaticozymmin have heretofore been primarily considered to be concerned with regulation of digestive activity of the pancreas, it now appears (from work especially of Dupré and Unger) that both of them can excite insulin release promptly when given by way of the portal vein in dogs or humans. Insulin release after pancreaticozymmin (but not after secretin) is accompanied by prompt rises in blood glucagon and glucose concentrations.⁸

The fact that these three substances can be shown experimentally to produce insulin release does not of course prove their role in the normal physiological response to glucose. The case for glucagon, however, is especially strong since it will release insulin in the isolated pancreas. In fact, since even in the isolated pancreas alpha cells (normally considered to be the principal source of glucagon in the body) are always present in intimate contact with the beta cell, it is at least theoretically possible that glucagon released from neighboring alpha cells could be an intermediate even in the so-called

“direct” release of glucose in the isolated pancreas.

Inorganic Ions

It appears that a minimal concentration of calcium is essential for the responsiveness of the isolated pancreas preparation to glucose and other substances. Thus this ion and perhaps a number of other substances may be important at least by way of a permissive effect. Potassium ion, in concentrations generally considered to be pathological (8 meq./L), has been shown to stimulate insulin release in the isolated organ.

Inhibition of Insulin Release

It was observed first in *in-vitro* studies and in animals, and later confirmed in human beings, that epinephrine and also norepinephrine are capable of suppressing insulin output with great effectiveness. In the human being this effect is especially striking since blood glucose rises sharply during intravenous administration of either hormone, while insulin levels remain low. As soon as the infusion of the catecholamine is ended, however, there is a very sharp and prompt rise in insulin levels, presumably due to the persisting high blood sugar concentration.

Recent work, especially by Porte (reviewed by Williams and Ensink⁹) has elucidated this interesting response further by the use of appropriate blocking agents in human studies. It appears that the suppressing of insulin response by epinephrine can be attributed to its alpha-adrenergic properties. When alpha-adrenergic receptors are blocked, it can be shown that epinephrine actually *stimulates* insulin release, this effect being mediated by beta-adrenergic receptors.

Neural Factors in the Regulation of Insulin Secretion

At the present time the greatest interest is centered on the possibility that humoral substances may mediate insulin release. However, it has been long known that both sympathetic and parasympathetic nerve fibers supply the pancreas, and that the possibility of neural control exists. The possibility of an important role by the vagus has been

strengthened by the demonstration by Frohman and others¹⁰ that electrical stimulation of the distal ends of both the left and the right vagus nerves in dogs produces sharp increases in insulin concentration in the portal vein.

Clinical and Physiologic Implications

The effect of blood glucose concentration on the beta cell is firmly established and it seems reasonable to assume that it plays a major role in the normal regulation of insulin secretion. It is now necessary, however, to consider the possibility that many other modifying factors may also play a significant part in insulin regulation. In fact, even the effect of glucose itself might be mediated by glucagon from the alpha cells of the islet. Furthermore, glucose may also act through another pathway remote from the pancreas (the ribose-responsive pathway).

Discovery of a "final common pathway" within the beta cell for the regulation of insulin release would resolve and simplify the present profusion of findings. Such a pathway would be sensitive to stimulation by glucose, mannose, and glucagon, and to suppression by epinephrine. It would also need to be sensitive to some signal — probably a metabolite — reaching it following the arrival of glucose or other carbohydrate

(such as ribose) and perhaps of amino acids as well, at a tissue site remote from the pancreas.

The nature of such a pathway must be a matter of pure speculation at the present. However, its sensitivity to both glucagon and epinephrine inevitably brings to mind the role of the cyclic nucleotide 3' 5' adenosine monophosphate (AMP) in the enzyme system for breakdown of glycogen.¹¹ To be sure, epinephrine and glucagon have very similar effects on liver glycogen breakdown, while their effects on the beta cell at present appear to be exactly opposite. In any case direct examination of this hypothesis will require direct study of the beta cell itself. See Figure 3 for a compilation of these ideas.

The most obvious and immediate *clinical* application of the material presented here relates to the management of the benign reactive or "functional" hypoglycemia seen in the adult, usually considered to be due to excessive insulin secretion after high carbohydrate intake. Since generous protein intake clearly can also lead to insulin release, the benefit of a very high protein diet in such persons now seems doubtful. The most sensible program would seem to be a regimen of frequent small meals containing

Fig. 3 — A diagram summarizing the factors which may play a part in the regulation of insulin secretion. Inclusion of cyclic AMP is hypothetical.

moderate amounts of both carbohydrate and protein.

While the newer information on insulin secretion has no immediate application to the clinical management of *diabetes*, there are important implications for the future. It seems likely that different forms or types of diabetes will emerge from the syndrome which is now characterized simply by hyperglycemia. In addition to the state characterized by a permanent incapacity of the beta cells to synthesize insulin (which is presumably the case in juvenile diabetes), it is likely that a syndrome may be defined in which the

capacity of the beta cells to synthesize and store insulin is perfectly normal, but the mechanisms for releasing this insulin are deranged. This may, indeed, prove to be the commonest form of diabetes — and also one in which rational treatment and even prevention may eventually be worked out.

Abdominal Muscle Deficiency Syndrome

This syndrome consists of (1) partial or complete absence of abdominal musculature; (2) hydroureter, hydronephrosis, and megabladder; (3) undescended testes in males; and (4) malrotation of the intestine. Fröhlich described the first case in 1839. Fifty-eight cases have been reported to date (Mathieu *et al.*), only four of which were females.

Deficiency or absence of the abdominal muscles includes the lateral groups, the transversus, and the obliques. The recti are often present. Symptoms more often pertain to the genitourinary tract or to one of the other numerous congenital abnormalities. These include pigeon breast deformity, spina bifida with myelomeningocele, hydrocephalus, congenital bladder neck obstruction, bilateral hydroureter, urachus, and perhaps talipes. The clinical course is often complicated by episodes of infections that require antibiotics and possible surgery. Many of these patients have a low intelligence quotient and require chronic institutional care.

Magendie Before a Class of Medical Students

Here, gentlemen, is the heart of a young woman who recently died in this hospital. I believe that I have already published an account of her case, which is one of exceptional interest; but, however this may be, I remember perfectly well all the details of the results ascertained (during life) by a careful auscultation of her heart. The first sound was heard without any difficulty, but the second one was entirely lacking. What, it will be asked, was the cause of this phenomenon? At first I was disposed to believe that she was affected with hydrothorax, but, when I came to make a more careful examination, I was obliged to reject this hypothesis; and, although I suspected that the absence of the second sound was due to an obstacle of a mechanical nature, — one that nullified the stroke communicated by the heart to the sternum, — I was unable to form any idea as to the real nature of this obstacle. The present autopsy furnishes the desired explanation. As a result of a former attack of pericarditis the anterior surface of the heart was covered with a thick layer of false membranes; . . . the tip of the organ, on the other hand, still preserved its usual smooth and polished aspect. . . . In my judgment the interposition of false membranes, which had been deposited upon the surface of the heart, acted as a cushion, thus preventing the transmission of the sound by annulling the shock which would otherwise result from the blow upon the sternum. Lower down, at the tip of the organ, where no false membranes had been deposited, the blow upon the thorax, caused with each systole of the heart, produced the normal degree of noise.

— Francois Magendie (1783-1855)

A Case History

The man, whose case history I am about to relate, said that the symptoms from which he had suffered, during the preceding twelve months, were the following: a frequent but dry cough, with loss of appetite; almost constant thirst; difficulty in obtaining sleep; night-sweats, more marked in the region of the head and neck than elsewhere; and irregular chills and fever. The physicians whom he had consulted were led to believe that he was affected with consumption, and they treated him in accordance with this belief, but so far without success. On examination I found that two of his teeth were carious, and I advised their extraction. A rapid restoration of the patient's health followed in less than a fortnight.

— Jean Petit (1674-1760)

The Middle Ages may have been a time of salutary delay. If it had exploited the earth's surface as we are doing, we would perhaps not be around at all.

Management of the Pregnant Patient with Complicating Diabetes Mellitus

WILLIAM N. SPELLACY, M.D.*
Minneapolis, Minnesota

PRIOR TO the discovery of insulin in 1921 by Banting and Best the great majority of diabetic women were considered infertile. The cause of infertility was usually a secondary amenorrhea, presumably due to hypothalamic failure resulting from the constitutional disease. When diabetic women did occasionally become pregnant in the pre-insulin era some 25 percent of the mothers and about 50 percent of the infants died.¹ Most of the women died with the characteristic picture of acidosis and coma shortly after delivery. Now, with insulin and more careful diagnosis, many more pregnant diabetics are seen. An awareness of the problems of this association is essential.

Incidence

With good control of diabetes fertility is almost normal. Thus this disease is seen in 0.2 to 0.3 percent of all pregnancies. Two different types of diabetes mellitus will be encountered. Most of the cases are insulin-dependent-juvenile-type diabetes, but as diagnostic acumen has improved, more of the maturity-onset-type diabetes are being recognized. Many of these are first diagnosed during a pregnancy.

A large volume of data has accumulated in recent years which shows that normal pregnancy is a stimulus to the pancreas. As a result, beginning at the end of the first trimester and progressing to delivery, there is normally an increasing amount of circulating insulin. This pregnancy-induced pancreatic stress can be demonstrated both morphologically in pancreatic beta cell hyperplasia and biochemically as hyperinsulinemia.²⁻⁴ The mechanism of this pancreatic stress is unknown, but it may be a reaction to increased growth hormone (either of pituitary or placental origin), estrogen, cor-

*From the Department of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minnesota 55455.
Presented at the South Dakota State Medical Association Meeting, Huron, South Dakota, May 23, 1966.

ticosteroids, or a placental insulin degradation ("insulinase") process.⁵ As a consequence of the unknown stress, late pregnancy becomes an ideal time to recognize those patients with limited pancreatic function. The characteristics of diabetes (or insulin deficiency as measured by blood glucose levels) may be found during pregnancy, only to disappear post partum. This has been termed "gestational" diabetes but is in reality early diabetes.

Diagnosis

The problem then is to alert the obstetrician to these changes during pregnancy and their interpretation. Tests for urinary sugars are frequently used. The urine of pregnant women often contains a reducing sugar which will give a positive Benedict's reaction. This could indicate: lactosuria, benign renal glycosuria, or diabetes mellitus. Since increased levels of blood lactose are normal near term and post partum, this reducing sugar should not be confused with the glucose of diabetes mellitus. During the last six weeks of pregnancy the frequency of lactosuria increases to about 8 percent and to 30 percent or more on the day before delivery. The more specific enzyme tests for glucose (glucose oxidase) will give a negative test with lactose.

Blood Glucose Abnormality

The increased renal blood flow and increased glomerular filtration rates associated with pregnancy will result in more molecules of glucose being brought to the renal tubules for any given blood glucose level. Benign renal glucosuria of pregnancy results. Because of this the diagnosis of diabetes mellitus during pregnancy can be made only on blood glucose abnormalities rather than on urine tests. Either a fasting blood sample or a glucose tolerance test can be used. Since there is an erratic gastrointestinal mobility and absorption during pregnancy it is advisable to use only the *intravenous* rather than the oral glucose tolerance test. This test eliminates the absorption variables and depends solely on utilization of the glucose load given. An example of the difference between the intravenous and oral test during pregnancy is

shown in Figure I. An erroneous diagnosis of diabetes mellitus would have been made from the oral test.

Management Dependent Upon Glucose Regulation

The glucosuria of pregnancy makes the clinical management of diabetics more dependent upon blood glucose regulation than on urine glucose control. Pregnant patients may have normal blood glucose levels and three to four plus urine glucose values. Treatment on the basis of urine glucose values in the usual way with a sliding scale for insulin dosage can result in maternal hypoglycemia.

Ketonuria

The glucosuria may be so severe in pregnant diabetics that most of their carbohydrate intake is lost into the urine. As a result their cellular metabolism will burn fat and produce mild ketonuria. This "starvation type" ketonuria is not serious and must be differentiated from true diabetic ketoacidosis where high-serum ketone-body levels are

GLUCOSE TOLERANCE TEST IN PREGNANT WOMAN

Blood glucose values for an oral and an intravenous glucose tolerance test on one-term pregnant patient performed at a three-day interval.

found. It can be treated by measuring the 24-hour urine output of glucose and increasing the carbohydrate content of the diet accordingly.

Maternal Problems

The maternal problems in diabetes during pregnancy include: shifting insulin requirements, hypoglycemia, acidosis, toxemia and hydramnios.

Shifting Insulin Requirement

With the known increased output of insulin by the pancreas in a normal pregnant patient it would be presumed that patients with pancreatic insulin deficiency, that is, those with juvenile diabetes mellitus, would need more exogenous insulin during pregnancy. Indeed, in most clinical series it has been shown that the majority of patients with diabetes will need more insulin during pregnancy.

Hypoglycemia

The extremes of glucose control present problems at different times during pregnancy. In the first half of pregnancy hypoglycemia is generally the problem. A common pattern is for the patient to take her morning insulin, eat breakfast and then because of "morning sickness," vomit her carbohydrate intake and become hypoglycemic.

Acidosis

Maternal acidosis becomes a problem primarily in the last half of pregnancy. There are several probable reasons for this: the increased need for exogenous insulin is not adequately satisfied²; there is a natural tendency toward acidosis in pregnancy, due to the diminished carbon dioxide combining power of the blood, and the frequent glucosuria in late pregnancy makes urine glucose values unreliable in the detection of impending ketoacidosis. The problem is very serious because almost all of the maternal deaths in diabetics today are due to acidosis, and there is a high association of fetal death in utero with maternal acidosis.

Toxemia and Hydramnios

The remaining two problems, toxemia and hydramnios, are associated with salt and wa-

ter retention. The incidence of toxemia in uncomplicated pregnancies is about 7 percent but in diabetics rises to 25 to 50 percent.⁶ The incidence of hydramnios in uncomplicated pregnancy is less than one percent, but in the pregnancies of diabetic women it is 5 to 30 percent.⁶ Both of these conditions are associated with a high frequency of fetal death in utero. There is no evidence that pregnancy per se will change the ultimate prognosis or course of diabetes mellitus.

Infant Problems

The babies of diabetic mothers present several problems which include fetal death in utero, congenital abnormalities, hypoglycemia, hyaline membrane disease, excessive size and diabetes mellitus.

Fetal Deaths

There is no increase in the abortion rate. The frequency of stillbirth is known to rise from mid-pregnancy until term and to be higher than in non-diabetic pregnancy. This is closely associated with acidosis and also with other maternal complications.

Congenital Abnormalities

The incidence of congenital abnormalities is about three times that seen in infants of normal mothers. Pedersen has shown the frequency to be directly related to the severity of the maternal diabetes.⁷

Excessive Size

The infants of diabetic mothers are usually larger than other infants, primarily due to fat deposition, and thus there is less body water per kilogram weight. There is also organomegaly. If severe maternal vascular disease is present small infants may result. Many factors may contribute to the large infants, including genetic factors, a hyperglucosemic environment (glucose readily passes the placental barrier), and increased production of growth hormone and insulin by the infant. The incidence of babies weighing 10 or more pounds, born to diabetic mothers, ranges in reported series from 15 to 25 percent, whereas this occurs in only 3 percent of non-diabetic mothers. Mothers

who have produced excessive-sized babies should be carefully investigated for diabetes. In experimentally produced alloxan* diabetes in rats, fetuses of excessive size were produced four times more frequently than in controls.⁸

Prognosis

Maternal

The risk for the diabetic mother is now very low. Hagbard found an over-all maternal mortality of 0.7 percent in 2,496 collected cases.⁹ Almost all maternal deaths today from diabetes complicating pregnancy are due to neglect.

Fetal

Most of the series reported an over-all perinatal mortality of about 15 percent. This varies, however, with the severity of the mother's disease. Since diabetes is associated with vascular disease and the severity of the vascular sclerosis is related to the duration of the disease, White et al. have devised a classification scheme of maternal disease severity from A through F. The perinatal mortality is directly related to the class of the mother's disease.¹⁰ Most authors agree that for a given class, the better the diabetic control (normal blood glucose values) the better the perinatal survival.

Management

In order to combat the complications listed above several principles of management are proposed.

Visits

It is suggested that the pregnant diabetic patient be managed by a team consisting of an obstetrician, an internist and a pediatrician. The patient must be seen frequently, at least every two weeks during the prenatal period. When any problems arise hospitalization should be arranged. Pedersen in Denmark has obtained excellent results by superb control during hospitalization for the last eight weeks of pregnancy.

Insulin

An important principle is to maintain nor-

mal blood glucose levels. This can be done by keeping the patient's diet and activities constant and adjusting her insulin dosage. The required insulin dose will increase in approximately two thirds of the patients; the remainder may need less or the same amount. The type of insulin used is not important. Since urine sugars become of little value during pregnancy, frequent fasting and postprandial blood glucose values must be obtained. Occasional quantitative checks of 24-hour urine glucose spillage is also helpful. A positive ketone body urine test should be checked with serum ketone levels. The insulin requirement usually decreases by one third to one half immediately post partum but by six months post partum is at the pre-pregnancy level. Insulin probably does not cross the placenta so that it will not harm the fetus. A falling insulin requirement near term is a poor prognostic sign, probably indicating decreased placental function and decreased "insulin-antagonist" production.

Diet

A constant dietary intake is essential for good control. White recommends 30-40 calories per kg. daily, including 150-250 grams of carbohydrate, 2 gm./kg. of protein, and the remaining calories in fat. In order to reduce water retention, a low sodium intake is begun at the first visit (2 grams Na.). The use of diuretics is also helpful, as they decrease the severity of toxemia and hydramnios but unfortunately not their incidence. The thiazide diuretics may raise blood glucose levels, but this can be controlled with more insulin if necessary. Breast feeding is not contraindicated, but a compensatory increase in dietary intake must be made. White has used exogenous estrogen and progesterone in treatment, but others have achieved as good results without these hormones.

Delivery

Because the incidence of fetal death in utero rises until term, it is recommended that infants be delivered between the 36th and 37th weeks of gestation, assuming that the infant is correspondingly mature. At this point one obtains the greatest total fetal

*See Test Your Word Score Page 363.

survival with an optimal relation between the risk of fetal death in utero and neonatal death from prematurity. Vaginal delivery following induction of labor is chosen when the usual criteria are favorable; but frequently at this period of gestation cesarean section becomes the only feasible means of delivery. The measurement of serial 24-hour urinary excretion of estriol has aided in the timing of deliveries, and a falling level is a poor prognostic sign, as shown by Greene.¹¹

Newborn Management

Since the infants have frequently been exposed to excessive amniotic fluid and have full stomachs at birth, immediate gastric suctioning is advised. They should be watched for hypoglycemia and respiratory distress and treated accordingly. Although the infants frequently have large birth weights, the organ systems do not always

function with corresponding maturity. Some authorities therefore recommend that during the first 72 hours of life these infants be treated with extra care. This includes an atmosphere of 40 to 50 percent oxygen, increased humidity, a temperature of 85°F. and frequent nursing observations.¹² Since diabetes has a hereditary tendency, there is an increased risk of diabetes in these infants in later life.

Summary

The management of pregnant patients with diabetes mellitus is becoming a more frequently encountered problem for physicians. A review of the problems involved and their treatment is given.

Green Medicinals

Herbs for the Digestive Organs

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them. Recommended for the digestive organs is a tonic easily infused for hops:

Hop Bitters

Take two ounces of buchu leaves and half a pound of hops. Boil together in an iron vessel in five quarts of water. When lukewarm add a pint of alcohol. — C. F. Level: Green Medicine

In addition to the lowly hops other aids to good digestion include convolvulus, Good King Henry,* meadowsweet, peppermint, rhubarb, silverweed, and Venus' looking-glass.*

Moliere on Doctors III*

The perennial hypochondriac vis-a-vis the exploiting doctor provides the theme for Moliere's Malade Imaginaire (The Imaginary Invalid), wherein the medical profession appears as a vast, autonomous entity: a monolithic, impersonal agency operating to perpetuate and vindicate its own power structure rather than to cure its humble patients.

In this farce Argan is the "imaginary invalid," whose bedroom ostentatiously displays a complete bar of medicaments prescribed by his physician, Dr. Purgon, one preparation for every malady that Argan is sure he is afflicted with.

Hitherto meek and obedient to his doctor's orders, Argan suddenly revolts at the prospect of being on the receiving end of a huge all-purpose syringe, to be administered by Dr. Purgon's apothecary. Outraged by his patient's heresy, Dr. Purgon shouts:

*"Here is a nice state of affairs! Never, in all my professional life, have I been so insulted. It was a Special and Most Extraordinary Mixture — never before administered to any living thing. One of my inspirations. It came to me, in one of the long watches of the night, and I arose — and prepared it for you, with my own hands. Every separate ingredient was to have had its own effect, upon your every ailment. It was to have cleansed your whole system — at one squirt. One squirt. I sent in my apothecary at the appointed moment, and he returned to me — the syringe unemptied, my miracle of healing unperformed — balked of his errand of mercy. And that constitutes not only a mortal insult to me personally, but to the whole Medical Faculty. You have destroyed, at one stroke, a sacred obligation — the unquestioning obedience of a patient to his physician. That is rebellion. The revolt of Ignorance against Authority. And in Medicine, as in Society, such behaviour must bring chaos and disaster. It cannot be tolerated. It must be nipped in the bud. And here and now. At once. And without mercy. You've brought this on yourself. I've done with you. I wash my hands of you. And leave you to your fate. Which — I may tell you — I don't envy you. In a short while from now, probably in a matter of hours, you will fall into a state of A-Pepsia. From that to U-Pepsia. From U-Pepsia to Mee-Pepsia. Then Drypsi-Pepsia. And from that in a condition of Bray-co-philial-Pepsia. And when the dread poison of that spreads into your every organ — as it must — then you will die — and horribly."****

Following this tirade Dr. Purgon departs in high dudgeon, abandoning the quaking Argan to his ordained doom — which, incidentally never materializes.

The Imaginary Invalid was written in 1673 and, like Moliere's earlier farces satirizing the medical profession, captivated French theater audiences with its witty dialogue and uproarious stage business.

Where there's a swill there's a sway. — Magazine Digest

Renal Vascular Disease Associated with Diabetes Mellitus*

J. M. B. BLOODWORTH, JR., M.D.**
Madison, Wisconsin

DESPITE MASSIVE strides in unraveling the riddle of intermediary metabolism in diabetes and the successful treatment of hyperglycemia, glycosuria, ketonuria and diabetic coma, the cardiovascular complications of diabetes have increased in number and significance. This increase in complications seems to be due to the increased longevity of the diabetic, which enables a subtle and probably low-grade pathologic chemical stimulus to gradually evoke the vascular changes over a period of many years. The kidney is a major recipient of the damage resulting from vascular disease.

Materials and Methods

Studies have been made of the kidneys removed from human diabetic patients at autopsy and percutaneous renal biopsies of living patients with diabetes. Tissues have been fixed in either formalin or osmium tetroxide† and prepared for light or electron microscopy respectively. For light microscopy, two micron paraffin sections were stained with hematoxylin and eosin or the periodic acid-Schiff technique. For electron microscopy, tissues were embedded in epon, ultra-thin sections cut on a Porter-Blum ultratome-2, stained with uranyl acetate, and examined in a RCA EMU-3G electron microscope.

Arterial Disease

It is generally accepted that the diabetic develops intimal arteriosclerosis at an earlier age, also that it progresses more rapidly and is more severe at any given age than arteriosclerosis in the nondiabetic. As far as we know, there is no definite difference in the distribution of arteriosclerosis in the diabetic. However, it seems to manifest itself most obviously in the increased incidence of

coronary occlusions, especially in the female diabetic, and by a high incidence of peripheral gangrene.

Arteriosclerosis is exceptionally severe in the diabetic kidney. However, because of the large reserve of the kidney and the concurrent microvascular disease which seems to be more universally destructive, death of a diabetic due to arteriosclerosis of the kidney alone is rarely observed. On the other hand, arteriosclerosis plays a prominent part in the renal destruction which finally leads to uremia in many diabetics.

Most investigators have pointed out that there seems to be no morphological or chemical difference (except intensity) between the arteriosclerosis of the diabetic and the nondiabetic. Recently, several studies, including one from this laboratory, have indicated that there is a slight increase in the glycoprotein content of the arteriosclerotic aorta from a diabetic patient. By electron microscopy, this finding is explained by an increase in the basement membrane material of the artery of diabetics, just as basement membrane is increased in the capillaries. In the artery, basement membrane surrounds the external surface of the endothelial cells, just as it does in the capillaries, and also extends peripherally to separate and surround each smooth muscle fiber. All portions of this basement membrane network are thickened in the arteries of the diabetic. The significance of this thickened basement membrane in passage of nutrients and wastes is still under investigation, and conflicting opinions now exist.

Diabetic Microangiopathy

This term has been coined to include all the microvascular disease of the diabetic; namely, the retinopathy, the diffuse glomerulosclerosis, the nodular glomerulosclerosis described by Kimmelstiel and Wilson, and the diffuse basement membrane thickening of most peripheral capillaries. This author believes that this term should be reserved for microvascular disease which has an unquestioned relationship to basement membrane and its glycoprotein metabolism. At the present time, there is some question in

some quarters as to whether the microaneurysms and other focal changes of classical diabetic retinopathy are due to the diffuse basement membrane disease of retinal capillaries — although they may well be. The kidney lesions of diffuse and nodular diabetic glomerulosclerosis are unquestionably basement membrane-oriented and are properly classified as a subdivision of diabetic microangiopathy.

Diabetic Glomerulosclerosis

This term seems most acceptable for the sclerosing, often nodular disease of the glomerulus in diabetics. The term intercapillary glomerulosclerosis should be discarded since electron microscopy has shown that the lesions are not between the glomerular capillaries but within the basement membrane of the capillary tufts.

Diabetic glomerulosclerosis begins as an almost imperceptible increase in the normal mesangial stroma and a generalized thickening of all capillary basement membranes. Because of the wide variation in the normal and the technical problems inherent in measuring basement membrane thickness, it is difficult to be sure how early this basement membrane thickness begins (i.e., in the prediabetic), but after five to ten years of diabetes in most cases glomerular capillary basement membranes will show from one and one-half to two times the normal thickness. The normal mesangial stroma consists of a few very thin, widely dispersed bands or fingers of basement membrane-like material connected to the surrounding basement membrane and interdigitating between the cells of the mesangial area. The normal mesangial stroma has been called "basement membrane branches" and "mesangial matrix." We use the latter term for the normal mesangial stroma. When the bands or fingers of basement membrane-like material of the mesangial area become not only increased in number but also many times thickened by the diabetic process, we refer to it as "hyaline matrix" because of its resemblance to hyaline and to differentiate the pathologic state from the normal stroma.

Diffuse Form

The first stage of diabetic glomerulosclerosis is the diffuse form. In our experience and as reported by most observers, there is always thickening of the basement membrane at this time. Kimmelstiel seems to be the lone dissenter to this opinion. At the same time there is a mild increase in the mesangial stroma or hyalinoid matrix associated with proliferation of mesangial cells

Fig. 4 — Glomerulus from a diabetic patient showing obliterative phase of glomerulosclerosis. Most capillary lumina have been occluded by the coalescence and expansion of nodules. Nuclei are beginning to disappear. One dilated capillary loop is present. Adhesions between the glomerulus and parietal Bowman's capsule are present (arrow). The arterioles show hyaline sclerosis. PAS-stain, 500 $\times$.

Fig. 5 — Glomerulus from a patient with long-term diabetes demonstrating exudative lesions. These lesions are dark and homogeneous in the photograph, with occasional areas of vacuolization. One crescent (C) is present covering the periphery of a capillary tuft, while other lesions are rounded (arrow) and represent filling up of entire capillary lumina by proteinaceous deposits. PAS-stain, 500 $\times$.

which have a large number of organelles* such as mitochondria, endoplasmic reticulum and ribosomes. These cells appear quite active and probably are responsible for the production of the hyalinoid matrix which lies between them. The thickening of the basement membrane proper is thought to be due to an increase in the production of chemically normal basement membrane material. To date there is no agreement as to what cell makes the basement membrane of the glomerular capillaries, although both the epithelial and the endothelial cell have been implicated. During the early stages of diabetic glomerulosclerosis, the diffuse form, the typical nodules are absent and the process is nondiagnostic. In fact, it is identical to the diffuse glomerulosclerosis of chronic glomerulonephritis or that produced by chronic liver disease.

Nodular Form

As the process continues, the diffuse form gradually becomes nodular. Nodules result from a slow and progressive increase in the amount of hyalinoid matrix and mesangial cells in the central region of each glomerular capillary tuft. Transition stages are frequently observed by both light and electron

microscopy, and there seems little doubt at this time that both diffuse and nodular glomerulosclerosis are stages of the same process. The typical nodule described by Kimmelstiel and Wilson in the diabetic kidney is composed of a core of interlacing bundles of hyalinoid matrix, among which are many mesangial cells and some nonspecific osmophilic debris. Usually the nodule is located peripherally in the glomerulus and is surrounded by open capillaries. The capillary basement membranes continue to thicken and may be two to five times the normal thickness by the time frequent nodules have developed.

Obliterative Stage

The third and most severe stage of diabetic glomerulosclerosis, the obliterative stage, has been observed more and more frequently in recent years, probably because of the better care and resulting longevity of diabetics. In this stage the nodules become quite large, often fusing, and compressing the peripheral capillaries until the capillary lumina are finally obliterated. Eventually, the glomerulus becomes completely ischemic and acellular. We refer to these glomeruli as the "large sclerotic glomeruli" to differentiate them from the "small sclerotic glomer-

*See Test Your Word Score Page 363.

Fig. 6 — Electron micrograph of a portion of a normal glomerulus from a nondiabetic patient. One complete capillary loop (C) is present and contains a red blood cell (RBC). Near the mesangial area (M) there is an endothelial cell with nucleus (EN) which sends a very delicate band of fenestrated cytoplasm (arrow) around the inside of the basement membrane (BM). The basement membrane is covered externally by an epithelial cell (EP) with foot processes and intervening canaliculi. 2700X.

Fig. 7. — Electron micrograph of a portion of a Kimmelstiel-Wilson nodule in the glomerulus of a long-term diabetic patient. The nodule is composed of a markedly expanded mesangial area composed of mesangial cells (M) and interlacing bands of hyalinoid matrix (H). Peripheral capillary loops (arrow) are almost obliterated. Basement membrane (BM) is markedly thickened. Epithelial cells (EP) have lost much of their normal foot process structure. 1700X.

uli" of ischemic obsolescence and glomerulonephritis. In diabetes the obliterated glomerulus is quite large due to the massive deposition of hyalinoid matrix within the stretched basement membrane of the glomerular capillary tuft. Bowman's space is usually obliterated by enlargement of the capillary tufts, and adhesions are frequent between the parietal and visceral layers of the epithelial cells. The adhesions are more frequent in regions of exudative lesions to be described below.

Hypertension

Although statistics show that not all diabetics develop hypertension and, in fact, less than 50% of diabetics with microangiopathy have hypertension, in our experience almost all diabetics who progress to the stage of obliterative glomerulosclerosis and die in uremia have hypertension and its attendant body-wide arteriolar sclerosis. Therefore, in many cases of nodular glomerulosclerosis and in most cases of obliterative glomerulosclerosis, there is also severe hyaline arteriolar sclerosis in the kidney. As many as 30% of the glomeruli may undergo ischemic obsolescence due to the arteriolar occlusions.

Exudative Lesions

Exudative lesions are frequently found in association with the typical nodules of diabetic glomerulosclerosis and are especially frequent in the obliterative stage of glomerulosclerosis. These lesions have been given many names: "hyaline-fibrinoid", "crescents", "capsular drops", etc. We prefer the single term, exudative, since the lesions seem to be present more often in rapidly progressive, end-stage diabetic kidney disease and appear to be composed of plasma constituents with a high concentration of fibrin. In the light microscope, exudative lesions have a very homogeneous, glassy, eosinophilic, PAS-stain-positive appearance or may be vacuolated or foamy due to a high lipid content. They are found between the basement membrane and the endothelial cell, or they may completely fill some capillary loops. They may also cover the external surface of a capillary loop outside of the basement membrane and thereby assume a crescent

shape, or they may occur between the epithelial cells and basement membrane of the parietal layer of Bowman's capsule (capsular drops). Electron microscopy has demonstrated these lesions to be composed of a fine granular, osmiophilic debris which closely resembles the hyaline of the arterioles and the glomerular deposits of adult membranous glomerulonephritis and lupus.

We have found small deposits of similar black, granular material on both sides of the basement membrane of the glomerular capillaries of diabetics. This material has the appearance and location of the deposits of glomerulonephritis. We have postulated that in diabetes there is formation of a foreign protein which is trapped in the glomerulus

Fig. 8. — Higher magnification electron micrograph of a capillary loop from a long-term diabetic patient. The lumen (arrow) is almost obliterated and non-functional. Endothelial cell (EN) and mesangial cell (M) are shown. Note the concentration of organelles in the mesangial cell, indicating protein synthesis. Basement membrane (BM) is markedly thickened and the epithelial cell (EP) has completely lost its foot process structure. Note the marked thickening of the delicate mesangial matrix which, because of its pathologic nature, is labelled hyalinoid matrix (H). 7500 $\times$.

in very low quantities over a long period of time and that occasionally these proteins may accumulate rapidly and in large quantities to form the exudative lesions. It seems possible that these deposits represent the injurious agent which is stimulating the formation of excess mesangial cells and possibly the abnormal production of mesangial matrix. These thoughts are speculative and must be considered in the light of the fact that we may be dealing with a number of coincidental occurrences of diabetes and glomerulonephritis in the same patient.

The End Stage

The "end-stage kidney of diabetes" is a mixture of arteriosclerosis, nodular glomerulosclerosis, obliterative sclerosis of most glomeruli, arteriolar sclerosis with massive hyaline deposits in the walls of most arterioles, microinfarcts of individual nephrons with small sclerotic glomeruli of ischemic obsolescence and associated necrosis or atrophy of associated tubules, numerous glomerular exudative lesions and foci of pyelonephritis, acute and/or chronic.

Metabolism of Basement Membrane

At the present time most investigators believe that the key to diabetic glomerulosclerosis lies in an understanding of the metabolism of basement membrane and its related pathologic material, the hyalinoid matrix. Basement membrane is a glycoprotein with approximately 10% carbohydrate. It is generally believed that the pathologically thickened basement membrane and the

hyalinoid matrix are chemically similar to normal basement membrane and the mesangial matrix, but markedly increased in quantity. The quantitative increase in this material may be due to excessive formation or to decreased turnover. Both theories have adherents. Lazarow found an amino-acid composition similar to that of collagen and reported a decreased turnover.⁶ More recently, Spiro has reported some amino-acid differences between the basement membrane and collagen.⁷ His studies of the basement membrane carbohydrates reveal the presence of galactose, mannose and hexosamine. There are differences between the carbohydrates of basement membrane and the carbohydrates of the plasma glycoproteins which happen to be elevated in most diabetics. Thus, the possibility of a relationship between plasma glycoprotein metabolism and that of basement membrane seems remote. Until further information is available on glycoprotein metabolism and basement membrane chemistry, the problem of diabetic microangiopathy will probably remain unsolved.

Summary

Diabetic glomerulosclerosis is the renal component of diabetic microangiopathy. It begins as diffuse thickening of capillary basement membranes and proliferation of basement membrane-like material and cells in the mesangial area. Later nodules form and finally the glomerulus is obliterated. Intimal arteriosclerosis is severe and contributes to renal failure, which often supervenes.

Mediastinal Emphysema Complicating Acute Asthma

Report of Two Cases

DAVID E. DINES, M.D.*
GUSTAVUS A. PETERS, M.D.*
Rochester, Minnesota

SPONTANEOUS DEVELOPMENT of mediastinal emphysema is a relatively rare complication of asthma that can be of grave concern and may even result in death. Herein reported are two examples of mediastinal emphysema complicating status asthmaticus and severe asthma with paroxysms of coughing.

Report of Cases

Case 1

A 29-year-old housewife was admitted to the hospital on March 3, 1966, in status asthmaticus. She had been asthmatic since seven years of age.

Physical examination revealed a dehydrated, dyspneic young woman with typical asthmatic wheezing. She had subcutaneous crepitation in the neck and a mediastinal crunch on auscultation.

Results of routine laboratory tests were normal except for eosinophilia of 10%. Results of acid-base studies by the Astrup method were within normal limits. A chest roentgenogram on admission showed mediastinal and subcutaneous emphysema (Figure 1).

The patient was treated with intravenously administered fluids, aminophylline, hydrocortisone sodium succinate (Solu-Cortef), Tedral, intermittent positive-pressure breathing with isoproterenol, and broad-spectrum antibiotics. She made a satisfactory recovery from the acute asthmatic attack, and only conservative treatment was necessary for the control of the mediastinal emphysema.

Case 2

A 19-year-old college student was admitted to the hospital December 27, 1965, with acute asthma. Two days before, she had experienced increasing difficulty with asthma, dyspnea, chest pain, vomiting, and severe coughing. She had a long history of asthma.

She had crepitation in the neck, axilla, anterior and posterior regions of the chest, and diminished breath sounds in the left base posteriorly. There were occasional inspiratory wheezing and sibilant rales.

Results of laboratory tests were within normal limits except for a 10% eosinophilia. Chest roentgenogram showed marked mediastinal and subcutaneous emphysema (Figure 2).

She was treated conservatively with prednisone, expectorants, bronchodilators, and high fluid intake and was asymptomatic when dismissed on January 6, 1966.

Discussion

Etiology

Payne and Geppert¹ in 1961 reported 32

*Mayo Clinic and Mayo Foundation: Section of Medicine.

cases from the literature. Either the condition must be a very rare complication of asthma or it is commonly overlooked.² It probably occurs more frequently than the medical literature indicates.³

Mediastinal and subcutaneous emphysema, associated with asthma, is believed to be due to an increase in intraalveolar pressure that causes rupture of alveoli adjacent to a bronchiole or pulmonary blood vessel. A forced expiration against a relative obstruction is generally necessary. Frequent increases in pressures as caused by coughing may also contribute. Air extravasates along the vascular sheaths and supporting tissues that extend to the mediastinum.

Air escapes into the subcutaneous tissues of the neck and down through the diaphragm into the retroperitoneal tissues, both areas acting as a safety-valve mechanism. Air may make its way forward over the heart, giving rise to a loud crunching sound (Hamman's sign) with each heart beat.⁴

Mediastinal emphysema from alveolar rupture occurs in adults with asthma, severe vomiting, labor and parturition, anesthesia, and violent coughing. A foreign body must

always be considered in a child. The same condition can occur from trauma with rupture of the lung, bronchi, trachea, or esophagus, and from carcinomatous involvement of the esophagus, trachea, or bronchi.

Diagnosis

Mediastinal emphysema can be recognized by a swelling and crepitation in the neck along with the mediastinal "crunch" on auscultation. The radiographic picture is characteristic. Air can be identified along the margins of the cardiac silhouette and adjacent to the pulmonary artery. The lateral chest radiograph is even more diagnostic (Figure 3) and shows air anterior to the heart, in front of the ascending aorta.⁵ Subcutaneous emphysema in the supraclavicular areas and in the region of the thoracic inlet was present in 13 of 16 cases.⁵ A lateral soft-tissue roentgenogram of the neck is helpful in identifying collections of air that have dissected upward into the neck along the paravertebral soft tissue.⁶

Prognosis

If a large amount of air is present, the

Fig. 1 — Typical pattern of mediastinal emphysema and subcutaneous emphysema apparent in the neck.

Fig. 2 — Mediastinal emphysema with subcutaneous emphysema of the neck, axilla, and anterior chest.

prognosis becomes more serious and surgical intervention should be considered. Death can occur from the pressure of air interfering with the return of blood to the right and the left atria, since the vena cava and pulmonary veins are thin-walled and have low pressures. Interference with venous return causes a low cardiac output, falling systolic and rising diastolic blood pressures, neck-vein distention, and finally cardiovascular collapse.⁷ Bilateral tension pneumothorax complicating mediastinal emphysema in asthma can cause death. A sudden critical increase in dyspnea associated with cyanosis, and pain confined to one side should direct suspicion to pneumothorax.^{8,9}

Treatment

The majority of patients should be treated conservatively. Cervical mediastinotomy¹⁰ may be necessary and, indeed, lifesaving if there is an indication of tension pneumomediastinum. Tracheostomy has been advocated by some¹¹ since it not only accomplishes mediastinal decompression but also decreases the intraalveolar pressure and affords a means by which secretions can be easily handled. Patients with tension pneumothorax are treated by surgical insertion of an intrathoracic tube and by water-seal drainage at negative pressures.

Intermittent positive-pressure breathing was administered to the first patient prior to recognition that she had mediastinal emphysema. Intermittent positive-pressure

breathing is contraindicated in patients with mediastinal emphysema and particularly where there is associated pneumothorax because of developing a tension pneumothorax and tension pneumomediastinum.

Fig. 3 — Lateral view shows air anterior to the heart, in front of ascending aorta, and in subcutaneous tissue of the anterior chest.

Drive Safely

Being physically present and mentally absent is one of the greatest causes of accidents. — Charles Kettering

The Madstone*

In 1905 Dr. R. G. Curtin of Philadelphia was taking care of a case of hydrophobia which attracted considerable attention in the daily newspapers. He was soon in receipt of many letters from all parts of the United States offering the use of madstones.

The following is from a number of the Waco (Texas) Examiner as quoted in the Boston Journal of Chemistry (1879) :

"Dr. C. F. Groves, the druggist yesterday paid Mr. Weir of Brown County the round sum of \$250.00 for the stone reputed a veritable madstone. Mr. Weir we are told found the stone in a deer in Arizona County, and we are further informed that it never failed to extract the poison of mad dogs, snakes, tarantulas and other venomous reptiles, insects and animals. The doctor will keep the stone at his store for the benefit of any one who may wish to test its virtues."

And in the Charlotte (North Carolina) Observer, the following news item appeared :

"Mark Carroll, of Blacksburg, came to this City, yesterday and received treatment with the madstone at the office of H. M. Wilder, corner of Tryon and Third Streets. The stone stuck to him for a period of thirty minutes, Dr. Wilder reports."

The matter-of-fact fashion in which these reporters tell their stories, indicates that they must have believed them. Surely there is no evidence that they or the editors doubted them. Lest it be thought that such news items represent merely past convictions, the reader is asked to consider the following advertisement which appeared in the Warren County Times, of Tennessee, in the year of grace 1933 :

"We have a madstone guaranteed to give general satisfaction for mad dog bites and all poisonous bites. Has been applied to hundreds of bites and never lost a case. Reasonable price. Rev. R. J. Tucker, Summitville, Tenn."

*Thomen, A. A., M.D.: Don't Believe It! Says the Doctor. Blue Ribbon Books, New York, 1935.

Plants vs. The Human Species

In our dealing with plants nothing of a painful nature is encountered; no sad images are ever presented to our eyes; there is absolutely nothing to recall to our minds our passions, our disappointments, our misfortunes; love is never associated with jealousy, beauty exists without vanity, force is never accompanied by tyranny, and death takes place without agony; in brief, there is nothing to remind one of the human species.

— Frederic Cuvier (1773-1838)

Derivatively Speaking

Do you understand the difference in meaning and derivation between the two similar words, *pylephlebitis* and *pyelophlebitis*?

Pylephlebitis: inflammation of the portal vein — from the Greek *pyle* (gate) + *phleps* (vein) + *itis* (inflammation).

Pyelophlebitis: inflammation of the renal pelvic vein — from the Greek *pyelo* (pelvic) + *phleps* (vein) + *itis* (inflammation).

Arteriovenous Fistula

An
Unusual
Cause
of
Heart
Failure
in
an
Old
Man

DAVID A. BERMAN, M.D.*
YOSHIO SAKO, M.D.**
JAFER KUAITY, M.D.†
Minneapolis, Minnesota

ARTERIOVENOUS FISTULA is a rare but curable cause of heart failure. This is a report on a 73-year-old man in whom spontaneous rupture of an arteriosclerotic left internal iliac artery aneurysm into the internal iliac vein resulted in high output heart failure. Surgical resection of the aneurysm and closure of the fistula, performed 20 years after the original diagnosis of the aneurysm and six years after the onset of congestive heart failure, resulted in dramatic improvement.

Case Report

A 73-year-old man was admitted to the hospital in March, 1966, because of increasing shortness of breath, orthopnea and ankle edema of three weeks' duration. A pulsating left-lower-quadrant abdominal mass had been present since 1946. At that time his blood pressure was 150/30 mm. Hg. and minimal cardiomegaly was noted on a chest x-ray film. He was free of symptoms and continued working until 1960, when he developed dyspnea and leg edema. Treatment with low-sodium diet, digitalis, rest, and diuretics resulted in prompt improvement, but subsequently he had repeated hospital admissions because of similar complaints. There was no history of back or abdominal pain, surgical operations, or traumatic abdominal injury.

Physical examination revealed an irregular pulse of 120 per minute; the blood pressure was 140/30 mm. Hg. The neck veins were pulsating and distended when the patient was sitting up. The cardiac apex was at the anterior axillary line. A grade 3, blowing, holosystolic murmur was heard maximally at the apex, also over the precordium and in the axilla. Crepitant rales and dullness were noted at the lung bases. A pulsating 8 × 4 cm. mass was palpable in the left-lower-quadrant of the abdomen and was also apparent on rectal examination. A thrill was present and a loud, continuous "machinery" murmur was audible over the aneurysm. The peripheral pulses were full and bounding. There was 2+ pretibial edema.

Generalized cardiomegaly and pulmonary vascular congestion were found on a chest x-ray film (Figure 1-a). An electrocardiogram revealed atrial fibrillation and increased voltage of the QRS complexes suggesting left ventricular hypertrophy. The urine sediment showed 80-90 red blood cells per high-

*Clinical Instructor of Internal Medicine, University of Minnesota Medical School.

†Resident in Internal Medicine, Mt. Sinai Hospital, Minneapolis, Minnesota.

power field. Right and transeptal left heart catheterizations were performed (Table 1). The results indicated biventricular failure, increased cardiac output and a large left-to-right shunt at the level of the bifurcation of the inferior vena cava. Minimal mitral regurgitation was observed on ciné left ventriculography. An aortogram demonstrated filling of a large aneurysm of the left internal iliac artery. Later films showed appearance of the contrast agent in the inferior vena cava (Figure 2). Dye dilution curves revealed an early and enlarged recirculation peak (Figure 3-a).

Surgical exploration revealed an aneurysmal dilatation of the left internal iliac artery. The artery was 8 cm. in diameter at its widest portion and tortuous, pushing the left common iliac and external iliac artery upwards and forwards. The terminal portion of the left common iliac artery was also involved in the aneurysmal process. Just inferior to the anterior rim of the true pelvis a

continuous bruit was palpable. Compression of the left internal iliac artery obliterated the bruit.

The internal iliac artery and the terminal portion of the left common iliac artery were excised and the aneurysm mobilized, but attempts to expose the actual communication with the vein were not pursued after an initial attempt because of excessive bleeding from multiple dilated and tortuous veins. Multiple deep suturing was done at the point of greatest bruit, and the internal iliac artery leading to and leaving the fistula was ligated and transected. A 10-mm. in diameter and 7-cm. long Dacron graft was inserted to bridge the defect between the common iliac and external iliac arteries.

Magnetic flow meter measurements of the common iliac artery flow before excision of the aneurysm were 1,440 cc./min., peak flow and 660 cc./min., mean flow. After excision of the aneurysm and closure of the fistula, the peak flow in the left common iliac artery was 780 cc./min. and the mean flow was 180 cc./min.

The removed specimen showed that the aneurysm was 11 cm. in length and 8 cm. in diameter and appeared arteriosclerotic. Following the operation, the blood pressure was 120/50 mm. Chest roentgenogram demonstrated a striking decrease in heart size (Figure 1-b). A repeat dye dilution curve showed a more normal contour (Figure 3-b). The subsequent postoperative course was entirely uneventful.

Discussion

Abdominal arteriovenous fistula may be caused by: rupture of an arterial aneurysm into an adjoining vein; a stab or gunshot wound; and operation for removal of herniated nucleus pulposus.¹ Internal iliac arteriovenous fistula related to trauma at childbirth has been reported in women.²

TABLE I
Cardiac Catheterization Data

Site	Pressure mm. Hg.	Site	O ₂ Content Vol %
LA	V = 30 M = 13	R. common iliac vein	8.2
LV	120/13	IVC bifurcation	11.7
PA	57/19 M = 30	IVC L4-5 interspace	14.1
RV	58/9	Mid-RA	12.4
RA	V = 15 M = 12	PA	13.5
		BA	15.3
Oxygen consumption = 204 ml/min.			
Cardiac output = 11.3 L/min.

RV = Right ventricle		M = Mean	

Fig. 1 — a (left) Preoperative chest x-ray film, Cardiomegaly is apparent. b (right) Postoperative film demonstrates marked decrease in heart size.

Rupture of an arteriosclerotic abdominal aneurysm is a catastrophic event in the natural history of this disease, but if the rupture occurs into a venous channel, the patient may survive for a time before succumbing to the resultant congestive heart failure. In this group of patients, the hemodynamic burden of a large left-to-right shunt may be placed on a patient whose cardiac reserve has previously been limited by coronary arteriosclerosis. Most of these patients die within a few weeks or months unless successful surgical closure is performed.³ The prolonged survival of our patient is unusual.

The diagnosis of a fistula between an abdominal arterial aneurysm and vein is not difficult. The presence of a thrill and a continuous "machinery" murmur over the aneurysm, with a widened pulse pressure and signs of heart failure, are the important clinical features. Dye-dilution curves are helpful in the diagnosis and localization of the fistula, particularly if the curve can be changed to a normal contour by compression of the fistula.⁴ Cardiac catheterization and angiography provide confirmatory evidence, but these studies are probably not essential in a typical case. In our patient the studies were done to assess the amount of mitral regurgitation and to exclude the possibility of an intracardiac shunt.

Hematuria observed in our patient has also been reported in other patients with this type of fistula and presumably is caused by venous congestion of the bladder.⁵ A more serious complication of aorta-vena-caval fistula is renal shutdown which has been reported as a cause of death in some patients.⁶

The first successful repair of an abdominal aortic aneurysm-inferior-vena-cava fistula was performed by DeBakey in 1954.³ Salem found 18 similar cases in the English litera-

ture from 1955 to 1965, of which 15 were operated and 13 survived.⁷

Summary

Rupture of an arteriosclerotic aneurysm of the left internal iliac artery into the adjacent vein produced heart failure in an old man. Surgical resection of the aneurysm and closure of the fistula resulted in immediate improvement.

Fig. 2 — a (left). Aortogram demonstrates a large aneurysm of the left internal iliac artery. b (right) Later film shows appearance of contrast in the inferior vena cava.

Fig. 3 — a (top). Preoperative dye curve. The early recirculation peak is suggestive of left-to-right shunt. b (bottom) Postoperative dye curve shows a normal recirculation peak.

Cook County Cervical Smear Clinic

THIS REPORT concerns the second annual "Pap Smear Clinic" sponsored by the Cook County Cancer Society. A highly successful effort by the Cancer Society, by volunteers, doctors, and public health officials of Cook County had resulted in the examination of 353 women during three clinics in April and May, 1965. Two carcinomas in situ were discovered, the women later obtaining curative treatment from their own physicians.

The same pre-registration techniques were followed after a "warm-up" publicity campaign. Practically the entire crew involved in this year's clinic were active in 1965 and the proceedings went smoothly throughout. Clinics were set for April 14, 22, 29 and May 6, 1966, with appointments at 10 minute intervals. This year only disposable supplies were used. A fee of \$4.00 was charged to cover costs of the special (reduced) fee charged by St. Luke's Hospital for reading the slides, and for supplies used. As before, all personnel involved donated their time and talents.

The information requested of each participant was slightly modified this year to conform to that requested by the A.A.G.P. form. All slides taken were sent to St. Luke's with the A.A.G.P. form; consequently each case automatically became part of the Academy's nationwide cancer detection project.

Results

A total of 373 women were examined and pap smears taken at the 1966 clinic. This figure is higher by 20 than the 1965 response. Only two women who were pregnant were seen at the clinic; the custom of not doing pap smears routinely on pregnant patients removes this segment of the population from clinic clientele.

Four cases of carcinoma in situ were discovered as a result of this clinic:

Clinic #	Age	Initial Pap Smear	Follow-up Pap Smear	Conization Report
101	42	Grade IV		CA in Situ
288	67	Grade IV		"
60	40	Grade II	Grade IV	"
135	36	Grade III	Grade IV	"

We found that 210 women who attended this clinic had been present at the first clinic.

A total of 163 women had their first pap smear this year. I found no obvious decrease in the number of office pap smears even during the month of the clinic itself. (I have kept track this year of the number of women seeking this test in my office, and also from Jan. 1st through Dec. 31, 1966, I have taken slides on 183 women). Thus the clinic approach does seem to reach a group of patients who are not ill and in whom a trip to the doctor's office for a pap smear tends to be postponed. It must be remembered that all four cases came from the "well" group of women, many of whom might not have bothered to see a doctor for the test.

The population of Cook county is about 3500 permanent residents. We estimate the adult female population at near 1,000 people. Thus 373 represents more than one third of the adult women. The additional 183 women seen in my office means that 556 women from this county have definitely had pap smears in 1966. In addition, it is certain a number of women will have had pap smears from the other physicians who see patients from Cook County.

Comments

It is my conviction, based on years of experience in dealing with enthusiastic volunteer lay groups helping in the conduct of "clinics," that community clinics offer the best, most inexpensive way devisable to apply mass screening programs of any type. The small town and rural communities in which I have practiced have never once failed to put over any such program suggested (i.e., cancer detection, immunization, tuberculosis testing). Our failure to help organize and participate in such programs costs people health and even life; participation repays a doctor with some of his most gratifying remuneration — the discovery that Medicine's "image" has grown just a bit less tarnished in the eyes of his fellow citizens. Undoubtedly mass community clinics will work better in small communities; however, an annual pap smear on over 50% of the adult female population of any community seems like a goal worth striving for.

Changes of Refraction and Diabetes Mellitus

SUDDEN AND often severe visual blurring frequently occurs as one of the more dramatic symptoms of diabetes. This blurring is due to an acute change in the refraction of the eye. This particular ocular change, while not so well known as the cataracts or retinopathy of diabetes, is of importance in that it may herald the onset of the disease or indicate poor control in an established case. Since Horner's original observation in 1873, much has been written about this subject. By 1925 Duke-Elder had collected 43 references from the medical literature. After the introduction of insulin, the refractive changes were observed even more frequently.

The essential features of the condition are the bilateral changes in refraction and their sudden appearance. An increase in the blood sugar causes a myopic change in the eye; conversely, a decrease in the concentration of sugar results in a hypermetropic change. The hypermetropic change does not occur as an initial phenomenon but follows a myopic change. The refraction commonly changes up to 2 or 3 diopters; Duke-Elder (1949) has recorded alterations ranging from -6 diopters to +9 diopters.

Initially, much speculation arose concerning the cause of these refractive changes, and many diverse theories to explain them appeared in the medical literature. Those dealing with changes in accommodation,

shortening or lengthening of the axis of the globe, changes in index of refraction of intraocular fluids, and changes in the corneal curvature have all been discarded on good evidence. By a process of elimination, plus the evidence reported by Elschnig in a case of unilateral aphakia* in which only the phakic eye showed the variations in refraction, the crystalline lens has become recognized as the site of changes producing alteration in refraction.

Three Theories

Although the lens is now agreed upon as the site, there is, by no means, agreement on the specific physical and chemical changes that account for the variation in refraction. Duke Elder (1949) states that three theories deserve mention: his own, that of Granström (1933), and that of Granström (1937), Bücklers, and Weekers.

Duke-Elder stated "... the myopia associated with a rising sugar concentration was due to hydration of the cortical layers of the lens relative to the nucleus. As the blood-sugar rises, provided the available water-reserve is maintained, the osmotic pressure of the aqueous tends to decrease, largely owing to the great elimination of osmotically active substances from the blood in the increased flow of relatively concentrated urine. The lens is a comparatively stable system, not readily participating in the fluctuations common to all the body fluids, and

Eczema of many years... controlled in two weeks

Before treatment

After treatment—
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side

effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive non-permeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

therefore it will tend to maintain its original molecular concentration; consequently, in order to establish osmotic equilibrium, fluid tends to flow into it from the chambers of the eye. The lens therefore swells and is deformed, its curvature being increased; further, the optical density of its peripheral layers becomes diminished while the nucleus remains unaltered. On both counts its refractive power is increased, and the eye becomes myopic. If the inflow of fluid is rapid, actual droplets are formed under the capsule of such a size that they can be seen with the slit lamp, or even with the loupe; eventually a cataract may be formed, sometimes with great rapidity. Conversely, with a fall in sugar concentration, a reverse osmotic flow is inaugurated, and a condition of hypermetropia is produced."

Granström's 1933 hypothesis states that hydration of the nucleus of the lens is responsible for the hypermetropic change. He suggested that in hyperglycemia salt is retained in the tissues and, on diminution of the sugar, hydration follows. The lens shares in these changes, these phenomena being more significant in the nucleus, since the cortex attains rapid equilibrium with the aqueous.

Granström (1937), Bücklers (1939), and Weekers (1949) independently noted that reversible changes in the lens of a precatactous type occur in some diabetics. They concluded that the myopia was caused by an increased refractive index of the lens owing to changes of a precatactous nature caused

by a toxic agent; such changes are reversible and, on their amelioration, hypermetropia results.

Of these three theories, that of Duke-Elder is most widely accepted by ophthalmologists. However, no less an authority than Adler differs sharply with it. Instead of hydration of the lens he explained the myopia as due to dehydration and stated that when the osmotic pressure of the fluid bathing the lens rises, the lens becomes dehydrated with a so-called dry salt retention. With dehydration of the lens, its index of refraction rises, causing an increase in its dioptric power and resulting in a myopic change. On the other hand, if the osmotic pressure of the aqueous is lowered, water is retained in the lens and its refractive index drops, resulting in hyperopia.

From the foregoing one may conclude that although the lens is clearly implicated as the site for the change in refraction, no agreement has been reached on the actual chain of events occurring in the lens. Whatever the mechanism of these changes, a sudden and seemingly inexplicable myopia should always suggest the diagnosis of diabetes. Occasionally, in a known diabetic, it heralds a derangement in the control of the disease. In any case, treatment should not be directed toward the eye but rather toward the underlying metabolic disorder, for the change in refraction is transitory and invariably disappears when metabolic equilibrium is achieved.

REGIONAL WEATHER FORECAST

Severe Snow Storms, Strong Winds and Bitter Cold Followed by Cough, Stuffed and Runny Noses and Aches and Pains.

Tussagesic breaks up coughs, quickly clears stuffed and runny noses and relieves aches and pains. Provide coverage of the tough cold for up to 24 hours with just a single timed-release tablet dosed morning, midafternoon and at bedtime.

each

Tussagesic[®]

timed-release tablet contains:

Triaminic [®]	50 mg.
(phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. **Side effects:** Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. **Precautions:** The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

Diabetes and Pregnancy

THERE ARE no problems for physicians in general practice, internal medicine, pediatrics or obstetrics currently more challenging and involved than those presented by the diabetic, gravid woman. The price of neglect during management of the pregnant diabetic is high: permanent damage, or even death, for mother and child. It is proper and timely that MINNESOTA MEDICINE devote some attention to the progress already made, the present state of our knowledge, and the host of still unanswered questions in this area.

During the last 35 years, dramatic improvements have been documented over the morbidity and mortality figures of the pre-insulin era literature on the pregnant diabetic and her child. Nevertheless, many unhappy effects of pregnancy upon diabetes, of diabetes upon pregnancy, and of both upon the fetus remain poorly understood. Debated issues include such problems as how to diagnose more pre-diabetics; the best ways to test for diabetes mellitus during pregnancy; the mechanism whereby pregnancy unmasks the pre-diabetic; the causes of toxemia and hydramnios, which occur much more frequently in diabetic mothers; the good and bad influences of hundreds of agents, hormonal, nutritional, placental and external (such as medications); the best time and method for delivery; the roles played by insulin hyper-secretion and insulin-antagonists in producing alterations of maternal insulin requirement; and what precautions help avoid loss of the baby, or prevent later difficulty in its development. Doctor William N. Spellacy, whose comprehensive article appears elsewhere in this issue,* has participated in extensive researches into some of these questions.

It has been pointed out that the frequency and severity of fetal troubles seem related to the duration of the diabetes, and the severity of the vascular complications, in the mother. However in any individual pregnancy, no matter how mild or how advanced

the disease in the mother, the same distressing (and sometimes fatal) difficulties may be encountered in the baby: excessive size; frequent respiratory distress; congenital anomalies; hyaline membrane disease; evidence that physiologic maturity lags behind anatomic development; and proneness to develop diabetes mellitus. Death in utero contributes significantly to the present perinatal mortality of about 15 per cent. Infant problems are described in Doctor Spellacy's contribution, and emphasis is placed on the value of good diabetes control in the mother: i.e., the better the control of the diabetes, the better the perinatal survival statistics, and the fewer the congenital anomalies.

Does pregnancy cause diabetes? It seems to accelerate its appearance in some women whose tendency to become diabetic was not recognized. Pregnancy also causes some such women to appear diabetic according to certain tests during some part of the nine-month period, only to return to apparent complete normalcy after the pregnancy. These and similar observations have led to use of the term "Pregnancy Diabetes," which has meaning only if employed with the above information in mind. Diabetes-prone individuals may have clinically obvious diabetes appear as a result of any stress. If we use the term "Pregnancy Diabetes," why not "Surgery Diabetes," "Severe Trauma Diabetes" etc., knowing that these events may have only hastened the clinical appearance of the disease?

Brevity is the soul of wit¹ but also a source of misunderstanding. It is true that serial 24-hour quantitative measurements of urinary excretion of estriol may help in choosing the optimum time for delivery.* A simpler and more commonly available test is x-ray for fetal bone age. The statement "there is no evidence that pregnancy per se will change the ultimate prognosis or course of diabetes mellitus" needs qualification. Hagbard² studied 250 diabetic mothers and reported that six months post partum, 67 per cent showed no large change in insulin re-

In peptic ulcer... antacid therapy with a new benefit

CONTAINS A BALANCED
COMBINATION
OF THE MOST WIDELY
USED ANTACIDS—
FOR RAPID
NEUTRALIZATION.
PLUS SIMETHICONE—
TO CONTROL
THE FACTOR WHICH
ANTACIDS ALONE
CANNOT INFLUENCE.

Mylanta[®]

- In Mylanta, aluminum and magnesium hydroxides are balanced to minimize the chance of constipation or laxation and still achieve rapid acid neutralization and pain relief.
- The positive action of simethicone helps relieve the painful gas symptoms which often accompany the peptic ulcer syndrome.
- The nonfatiguing flavor and smooth, nongritty consistency of tablets and liquid encourage continued patient cooperation during long-term therapy.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) of liquid contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. **Dosage:** one or two tablets, well chewed or allowed to dissolve in the mouth, or one or two teaspoonfuls of liquid to be taken between meals and at bedtime.

The Stuart Company, Pasadena, California
Division of Atlas Chemical Industries, Inc.

Stuart

quirement, 16 per cent required in excess of 12 units more for good regulation, and 17 per cent required more than 12 units less. These figures seem to cancel out statistically, but for each of the 83 diabetic mothers affected, the shift in insulin requirement of over 12 units can hardly be cited as evidence that pregnancy per se does not change the course of diabetes mellitus.

We may not wish to go to such lengths as does one Scandinavian clinic, which hospitalizes every diabetic mother twice during

pregnancy: briefly in the first trimester for strict regulation, then again from the thirty-second week until delivery. However, by using the team approach (general practitioner or internist and obstetrician and pediatrician) and requiring the strictest possible regulation of the pregnant patient's diabetes — based on present knowledge, we too can promise mother and child the best chance of a normal future.

Insulin, Diet and Diabetes

IT HAS BEEN said that the discovery of insulin set back research in diabetes by at least twenty-five years. Everyone became preoccupied with the problems of treatment rather than the causes of the ailment. When the sulfonylureas were discovered thirty-five years later we still had no knowledge of the cause of diabetes mellitus.

Concern with the presence of sugar in the urine has led to recognition that at least two sugars other than glucose may be present without real diabetes mellitus being present. The same concern with glycosuria has certainly blinded us to the far-reaching disturbances that characterize diabetes mellitus. It seems that we measure the amounts of glucose in the blood and the urine because we are too ignorant to measure anything else.

Forty-five years after the discovery of insulin, we still do not have criteria for the diagnosis of diabetes mellitus. Not only do we not have figures for the normal glucose values in persons over fifty years of age, but there is even a question of how diagnostic the glucose tolerance curve may be in persons under fifty.

Dr. Bloodworth* has summarized the basement membrane changes in renal capillaries in diabetic nephropathy, but what is

the significance of the same changes in the child of diabetic parents who has not yet shown changes in glucose metabolism? Is he a diabetic or even a pre-diabetic; or is he only a histologic curiosity?

Perhaps no disease state outside of the general field of neoplastic disease or the problems of aging has been so intensely studied in its superficial or peripheral manifestations without having its basic defects or causative factors defined.

The objective in the day-to-day control of diabetes mellitus is primarily the maintenance of a state of normoglycemia. This is generally accomplished by the use of insulin and the periodic determination of the blood-sugar level or the extent of glycosuria.

We should not overlook, however, a fundamental contribution to the science of diabetic management by a man who was not a physician but a biochemist. The name of Somogyi is usually associated with the method of determining the true glucose content of the serum; however, he proposed a still more useful concept that has been too long unappreciated; namely, the concept of glucose utilization as an index of adequacy of control: a consideration more important, we believe, than concern for the amount of glucose lost in the urine. The proposed ideal in dietary and insulin management of diabetes

should be the highest ratio between the amount of glucose utilized in grams per day and the units of insulin required each day. Rather than raising the insulin dose to cover the glucose lost, Somogyi proposed that the glucose ingested might be lowered in order to avoid excessive wastage. Certain British clinics currently achieve this end by pre-

scribing only the carbohydrate limitations in the diabetic diet, leaving the protein and fat to find their own levels, depending on the patient's needs and appetite. This is really the essence of practicality in diet prescription.

Prevention of Neonatal Death*

IT IS TRAGIC to admit, but statistically valid, that — despite our most sophisticated techniques of treatment for the Rh-sensitized pregnancy — there still remains an 8% to 10% neonatal death rate in such cases. The present forms of therapy reveal their inadequacy in several stages of the approach.

Initially, if every pregnant woman is not screened for irregular antibodies other than ABO and D, hemolytic disease may become manifest when least expected. Typing for other factors in the Rh system and in other blood groups need be done only if screening of the mother's serum demonstrates an irregular antibody. The test cells for screening should contain all red-cell antigens likely to cause hemolytic disease. Irregular antibodies known to cause hemolytic disease generally belong to the incomplete immune globulins.

Secondly, when positive titers and amniotic-fluid densities forewarn of impending disaster, we cannot accurately forecast fetal ripeness; for there is as yet no reliable method of determining fetal maturity, especially when one is operating purposely close to the grey zone of immaturity. Parenthetically, too many amniocenteses are still being performed without attempts having been made to locate the placenta. Placental tissue transgressed by needle puncture transports fetal cells into the maternal circulation, thereby exaggerating an already critical situation by introducing additional antigens riding on fetal cells into the maternal system.

Lastly, intraperitoneal fetal transfusion must be regarded as a formidable procedure carrying with it both fetal and maternal

morbidity and perhaps mortality. Although teams of trained individuals frequently exposed to the variables of the procedure can minimize complications, additional reports of difficulties undoubtedly will appear in our obstetric literature.

More effort must be directed to our most recent approach to the problem: namely, prevention rather than detection and therapy. At present we administer high-titer anti-Rh globulin to the immediate-post-partum Rh-negative woman whose ABO system is compatible with that of her husband. The rationale for administration of the anti-Rh γ -globulin is based on the original findings of Theobald Smith who demonstrated in 1909 that neutralized mixtures of diphtheria toxin and antitoxin containing an excess of antitoxin did not immunize when injected. If a specific antibody is administered passively to an individual, subsequent injections of the corresponding antigen will usually fail to sensitize. However, the level of the passively administered antibody must be sufficient to maintain an excess at all times.

Before final evaluations can be written regarding the procedure, we must continue to improve methods for quantitating minor populations of fetal red cells in the maternal circulation and maintain a close follow-up of patients who have received the γ -globulin throughout several pregnancies. Efforts thus made may ascertain when sensitization actually occurs in a particular pregnancy, with perhaps future use of anti-globulins during pregnancies in which sensitization would ultimately occur.

'Thorazine' is useful as a specific adjuvant in the above named conditions.

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*. **Contraindications:** Comatose states or the presence of large amounts of C.N.S. depressants. **Precautions:** Potentiation of C.N.S. depressants may occur (reduce dosage of C.N.S. depressants when used concomitantly). Antiemetic effect may mask other conditions. Possibility of drowsiness should be borne in mind for patients who drive cars, etc. In pregnancy, use only when necessary to the welfare of the patient. **Side Effects:** Occasionally transitory drowsiness; dry mouth; nasal congestion; constipation; amenorrhea; mild fever; hypotensive effects, sometimes severe with

I.M. administration; epinephrine effects may be reversed; dermatological reactions; parkinsonism-like symptoms on high dosage (in rare instances, may persist); weight gain; miosis; lactation and moderate breast engorgement (in females on high dosages); and less frequently cholestatic jaundice. Side effects occurring rarely include: mydriasis; agranulocytosis; skin pigmentation, lenticular and corneal deposits (after prolonged substantial dosages).

For a comprehensive presentation of 'Thorazine' prescribing information and side effects reported with phenothiazine derivatives, please refer to SK&F literature or *PDR*.

Arterial Injuries

THAT ARTERIAL injuries demand prompt attention is an accepted surgical principle. An important article by John J. Bergan, M.D., appearing in the September issue,* points out the fact that iatrogenic arterial injuries are no different from those caused by trauma of any other kind.

There exists in every physician a reluctance to accept the fact that he has, through his action, caused harm to his patient. The physician must hurdle this emotional barrier before he can properly diagnose and treat iatrogenic arterial injury; but if he has disciplined himself to "stand apart" and view the problem objectively, little time will be lost because of his emotional involvement.

Dr. Bergan discusses arterial injuries occurring in the operating room. These may become less common or at least be more adequately handled in the future, since graduates of most approved surgical training programs now acquire a substantial exposure to vascular surgical techniques. He points out, however, that diagnostic procedures which necessitate arterial puncture now constitute the most common cause of iatrogenic arterial injury. More and more of these procedures are being performed by persons without appreciable surgical

training, such as the cardiologist and the radiologist. It does not seem practical that these diagnosticians should train themselves as vascular surgeons. They must, however, be willing to function as clinicians and draw appropriate conclusions from the patient's symptoms and the findings of physical examination. This will be a new experience for the radiologist, but will, I believe, make his work more exciting.

To make his procedure as safe as possible the diagnostician should see and evaluate his patient beforehand. He should adopt a schedule of pre-medication that will sedate the patient properly (the most important factor in the successful performance of a local anesthetic procedure). He must follow and examine his patient after the procedure for at least 24 hours. He must discipline himself to accept the signs of arterial injury and promptly seek help from the vascular surgeon when indicated. He should consider avoiding such procedures if vascular surgical help is not available in his community. Then the arterial injuries which are inevitably incurred in the performance of such diagnostic procedures will be handled with the least morbidity and best possible result.

Abdominal Arteriovenous Fistulas and Congestive Heart Failure

IN THIS ISSUE* there is a case report of "an unusual cause of heart failure" by David A. Berman and colleagues. This interesting case deserves further comment. An abdominal arteriovenous fistula is certainly an uncommon cause of congestive heart failure, but its recognition is important because of the potentially curable nature of the lesion. Recently I had two patients with this problem. Although the correct diagnosis was made within two weeks after the rupture of

the aneurysm, in each instance the outcome was jeopardized by the lapse of time after the formation of the fistula.

Review of the Mayo Clinic files back to 1919 revealed five cases of aortocaval or iliovenous fistula. All were associated with congestive heart failure—one with chronic failure such as reported by Berman and co-workers. It should be emphasized, however, that abdominal aortocaval fistulas usually cause large left-to-right shunts and, subsequently, acute high-output cardiac failure.

Repair was successful in one of the five cases from this institution; in this case a clot occluded the lumen of the fistula. Perhaps clotting in the fistulous tract is associated with a longer survival, such as in the case reported by Berman and co-workers. The abdominal aortic aneurysm may be small and not palpable, but certain clues on examination of the heart and pulses should alert the clinician to listen carefully over the abdomen and lower part of the back for the diagnostic bruit. The bruit may or may not be continuous. The bounding carotid pulse with a wide pulse pressure in the absence of a murmur of aortic insufficiency strongly suggests rapid runoff through a peripheral arteriovenous fistula. Central fistulas of the lungs are not associated with these findings. Signs of right heart failure secondary to venous overloading are found in the acute cases of heart failure. These findings include a right ventricular lift on palpation, with marked increase of the jugular venous pressure. A large V wave with a holosystolic murmur at the left sternal border suggests the presence of tricuspid insufficiency. Mitral insufficiency may be present because of dilatation of the mitral annulus.

In one of our cases, the patient presented with severe venous insufficiency of the right lower extremity. The leg was blue and markedly edematous, but the pulses were intact.

In addition, rupture of the abdominal aortic aneurysm into the inferior vena cava can simulate acute low back pain from a ruptured intervertebral disk. Indeed, the fistula

may result from surgical trauma in the removal of such a disk.

A thoracic roentgenogram usually is not helpful except to exclude the presence of a thoracic aneurysm. Shortly after the formation of the fistula, the electrocardiogram may indicate right ventricular strain with a shift in the frontal axis to the right. Special procedures such as cardiac catheterization are not absolutely necessary and may be contraindicated in a severely ill patient. Although thoracic and abdominal aortograms may be occasionally helpful in localizing the fistula, often they are not because of the rapid runoff through the tract. The clinical picture of congestive failure, bounding peripheral pulses, warm extremities, and a continuous abdominal bruit is sufficient evidence to warrant abdominal exploration without special procedures.

One final note is about the use of digitalis in patients with arteriovenous fistula and congestive heart failure. The drug should be administered with caution. It is likely to be less effective than when given for low-output congestive failure. Cardiac arrest occurred postoperatively in one of our patients. He had been digitalized rapidly in the 24 hours prior to the operation, and repair of the fistula caused a sudden, profound diuresis. In retrospect, perhaps rapid shifting of the electrolytes and potassium excretion predisposed this patient to severe digitalis intoxication.

Carlos E. Harrison, Jr., M.D.
Rochester, Minnesota

Surgery on the Extracranial Vessels

THE ARTICLE by Garamella, et al.* in the November issue of MINNESOTA MEDICINE adds to the growing literature on the subject of surgery directed towards the extracranial blood vessels. They summed up the problems inherent in this subject when they stated, "Admittedly, the functional results are more difficult to evaluate than anatomical corrections made, and long term studies

are necessary for further elucidation." In short, the restoration of blood flow in a vessel cannot be equated with the return of function of the nervous tissues supplied by this vessel.

The natural history of arteriosclerosis of the carotid and vertebral arteries is not completely known and further information on this subject is urgently needed. There is ample evidence that complete or partial occlusions of the extracranial vessels may be present without interference with cerebral

function.^{1,2,3,4} The collateral circulation is sufficient to avoid any functional impairment.

Another serious question to be answered is the role of surgery and anticoagulant therapy vs. no therapy in this group of patients. Control studies are necessary in which comparable patients are divided into three groups: those who receive no treatment; those who receive anticoagulant treatment, and those who have repair of the involved vessels.

In order to be able to assess the results of surgery directed towards the extracranial vessels, careful study of the patient's status prior to and subsequent to surgery is indi-

cated. In this area, the majority of general surgeons are of necessity dependent upon evaluation of the status of the cardiovascular and nervous systems by consultants, as they themselves are not particularly trained in diseases of the brain and cardiovascular systems. Only by careful documentation prior to and subsequent to surgery of the patient's functional status can any reasonable conclusions be drawn; therefore a team effort directed towards this evaluation is to be encouraged.

The field of surgery on the extracranial vessels is in its infancy. Far more experience is necessary before any final conclusions can be drawn as to the efficacy of surgery and the indications for it.

You May Be Right

"Only 53 cases have been reported in the English literature."

What is meant by the term "English literature?" Is it to be differentiated from Scottish or Irish journals; or is it to include American journals?

It seems that the word English when used as an adjective still carries a sense of pertaining to England. One would hardly expect to find the writings of Mark Twain in a college course of English literature. However, few of us consider that we talk American but rather English, regardless of whether we are natives of Jamaica, Hong Kong, Cork, or Los Angeles. It seems that when we want to express the fact that we have abstracted articles written in the English language we had best refer to them as papers in English rather than English literature.

So, in this instance where most of the cases had been reported in American journals, "only 53 cases have been reported in English" is to be preferred.

Raymond C. Read, M.D.

The Editor's Soliloquy

"I've Got You Down for a Thousand"

It was late March and the income tax deadline was imminent. Our accountant, an enthusiastic Disabled American Veterans advocate, had come over to examine the books. Together we analyzed almost everything: our income and outgo, our profits and losses, and the numerous possible deductions for this and that, some of which were acceptable, others not. Contributions to the church, civic opera, art museum, community fund and various minor charities, as well as auto, convention, and entertainment expenses if incurred for business purposes: all these were deductible.

But not the paint job on the garage door, the lawn fertilizer, the snow removal, the frozen radiator, the installation of a picture window, the addition of a balcony, etc.

I was vicariously gratified, however, to learn that *if* I were a professional band director the initial cost and subsequent upkeep of my uniform would be deductible. Also my equine expenses, were I vocationally engaged in breeding and selling race horses.

Finally, when we had completed our examination and were relaxing with a cup of coffee to finish off the evening, a sudden after-thought shattered my complacency.

"Just one more thing, Doctor. The D.A.V.! Those boys in the blue caps and jackets — on the street corners — with slotted tin cups — and forget-me-nots! Whatever you contributed is deductible, you know. You may as well include it. How much was it?"

"Ten cents."

"WHAT!"

"Well, would you settle for a dollar?"

Our Senior Educators

Miss Gertrude M. Gilman

Miss Gertrude M. Gilman, Director of the University of Minnesota Hospitals, is one of the few woman administrators of a big university teaching hospital in the country. Her achievements and contributions are impossible to measure, as she has pursued her career in such a quiet, dignified manner that the impact of her influence is impossible to calculate.

She was born in Benson, Minnesota. Her father, Ira C. Gilman, came from Sioux Falls, South Dakota, and her mother, Minnie Neason Gilman, from Blockley, England. She has one brother, Neason Gilman, now living in Florida. Her father died in 1913 and her mother in 1947.

Continued

Miss Gilman graduated from the University of Minnesota in 1921. She planned to become a teacher but began work in the University Hospitals shortly after graduation from college and never left. Her personnel records show a steady progression through many positions to the Director of the Hospitals and Professor of Hospital Administration.

Through the years she has had a strong influence in molding the Hospitals' programs and in developing warm personal relationships with the physicians of the state, County Commissioners and directors of social agencies. Her professional career parallels the development of welfare programs from direct contact with probate judges, County Commissioners, County Welfare Departments, and Social Security up to the present Medical Assistance and Medicare.

She has had a part in the development of the institution from a small building of 120 beds to a great complex of 830 beds and a staff of almost 2,000. When Miss Gilman began as the Director of the Admissions Department, only the poor, the most indigent came for care. The same institution she now directs takes care of people of all financial circumstances who come from all parts of the world to receive help.

One of the important points in her career probably came when Mr. Ray Amberg was appointed director of the outpatient department in 1929. At that time the Eustis addition and the Out Patient Clinic building were attached to the Hospital and made one institution. Miss Gilman became the Admission Director for the Clinics as well as for the Hospitals. This early recognition of her abilities and expansion of her functions brought her directly into policy-making and administration. This also was the beginning of a long association and close working relationship with Mr. Amberg.

The Director of Admissions holds one of the most important positions in a medical setting. The income of the institution, the relationships with physicians, community leaders, patients and other interested people all depend upon the manner in which this position is filled. Mr. Amberg, Director of the Hospitals, established liberal policies which Miss Gilman carried out. He believed sick people should be helped whenever they were in need of the services the University Hospitals and Clinics could provide. Each specific situation was reviewed and the attempt made to extend the services of the institution to patients and physicians. Miss Gilman was particularly adept in establishing a warm bond of friendship with physicians practicing in all parts of the state. Many she knew as students and internes and they were accustomed to her being in a position to be helpful to them.

Influence on Teaching Program

The Out Patient Clinics were considered an essential adjunct to the teaching program of the Medical School. Mr. Amberg and Miss Gilman believed the interests of medical education could best be served by liberal admission policies to encourage doctors, agencies and patients to use the services. In this way the clinics were able to provide a wide scope of medical conditions and diseases to enhance the teaching program and facilitate the students' learning experience. This was a most difficult course to follow in those early days and required great tact and diplomacy.

Physicians often accused the University of taking business away from private doctors or of providing medical care for people who could afford to pay physicians' fees. The financing of medical care had to be authorized by the County Commissioner of the patient's legal settlement. This required tact and great ability to interpret the medical needs and the responsibility for providing medical care. Miss Gilman's diplomacy, patience and gentle manner were most successful in these areas. If this function had not been so thoughtfully carried out, the Hospitals would not so easily have been able to change the groups served and become an institution predominantly serving patients who pay their own expenses. One of Miss Gilman's greatest contributions was the excellent relationships she was able to build with all groups: patients, physicians and the general public.

Coordinating Department Heads

Of all the administrators, Dr. Louis Baldwin, Mr. Paul Fessler, Dr. Hulbert Dunn and Mr. Ray Amberg, under whom Miss Gilman worked, Mr. Amberg had the greatest influence on her career. Her advancements parallel his; as he was promoted, he increased her areas of responsibility. It is not often that a hospital is so fortunate in having a pair of administrators who work so well together and complement the talents of each other so completely. Mr. Amberg believed that department heads should run their own departments as independently as could be allowed within the structure of his administration. As much help as was needed was available and that help often came from Miss Gilman. After the opening of the Mayo addition in 1956, the institution became a large formal operation. Miss Gilman was able to assume the responsibilities for the management of the Hospital, leaving Mr. Amberg free to make a tremendous contribution to the American Hospital Association as its President, to participate in lobbying important health and welfare legislation through the Congress, and to build a firm foundation for the institution in Minnesota.

Everyone on the staff of a teaching institution has an obligation to participate in the educational program. The University Hospitals, as a part of a great University, has taken a position of leadership in training personnel essential to medical care. The various departments carry out full teaching programs and are themselves similar to small colleges. Dietetic Department, Medical Technology, X-Ray Technicians and the five schools under the Department of Physical Medicine are all lodged in the hospitals and under the direction of the staff assigned to direct the departments. Other departments of the University send students to the Hospitals for training, e.g., Schools of Hospital Administration, Pharmacy, Dentistry, etc.

A Program of Hospital Administration

Miss Gilman's contribution to the program of Hospital Administration is certainly one of the greatest of her career. While she has indisputably achieved recognition in administration, her influence as an educator deserves equal merit. The students whom she directed through their year of

Continued

internship acquired her compassion for people and her devotion to patient care. They learned the art as well as the technique of administration. Many of the students she has taught over the past years now hold important positions throughout the country. Miss Gilman has participated directly in all the other areas of the Hospitals' teaching program through special lectures and conferences.

Genteel Dignity

In reviewing such a steady, successful career, particularly in such a masculine and competitive field, it is essential to attempt to distinguish those personality factors which have influenced, if not produced, such a remarkable career. To those who have known and worked with her over the years Miss Gilman presents many outstanding personal attributes. The most obvious is her genteel dignity. She is quiet, a lady in the true sense and always in command of herself and the situation in which she happens to be. She is an excellent executive and gets her points across in a mature way without the need for undue emotion. She is a humble person, sensitive to the needs of others, and a person of genuine integrity. All through her career, in every position, her focus has been on patients. She has never let her responsibilities for the development of programs, administrative structures or policies deflect her concern for people. If she was ambitious for herself, no one ever sensed it. Each promotion she seemed to meet with surprise and simple gratitude. She never pushed or jockeyed for position but rose to the top on pure merit.

In her dealings with staff and personnel she is always fair and understanding. She is able to translate her feelings and opinions most directly in a manner which leaves little room for misunderstanding, but she does so in a genteel manner, sensitive to the feelings and objectives of her staff.

Another of Miss Gilman's attributes which has contributed to her success is her phenomenal memory. She seldom forgets a name, a face, or a situation. Many people with excellent memories can recall unusual events, but she can remember both unusual and ordinary, a marvelous asset for a Hospital Administrator, as this allows her to keep thousands of facts in mind.

Organizational Activities

Miss Gilman has participated in the activities of many professional organizations. She served as a member of the Committee on Nursing, Liaison Committee of the National League of Nursing, American Hospital Association, Steering Committee of the Minnesota League for Nursing, and Chairman Administrative Practices Committee and Twin City Regional Hospital Council, President's Report 1958-60.

She also served as a member of the Committee on Nursing of the American Hospital Association, Hospital Nursing Service Liaison Committee, Advisory Committee of Study to Project Future Needs for Nursing in Hospitals, Committee on Nursing Service and Education in National Defense, Committee on Careers of the National League for Nursing, Joint Committee of the American Hospital Association and American Dietetic Association, trustee of the Twin City Regional Hos-

pital Council, member of the Chaplaincy Committee Greater Minneapolis Council of Churches, and member of the Health Committee of the Community Health and Welfare Council of Hennepin County.

Miss Gilman's has been a professional life of sincere devotion to the Hospitals. Though this has been her consuming interest, she has still been able to achieve a balance between professional and personal life, a unique achievement. Her interests outside of her job have been the simple relaxing pleasures of most women — family, home, travel, and friends.

Miss Gilman has a home and garden at 4209 Aldrich Avenue South. Miss Ione Corliss, for many years Director of Nursing for the Out Patient Department, lives with her. Miss Gilman takes frequent trips to Florida to visit her brother and his family and has made several trips to England to visit relatives and her mother's home community.

Her life at the University of Minnesota Hospitals is characterized by devotion to the task of providing medical care to people. That devotion has been emulated by her students and staff. Her influence has been extensive and thousands of people live happier, more satisfactory lives because of her 42 years of dedicated efforts in their behalf.

Pleural Effusion

QUESTION: I have a 24-year-old male patient who developed a left pleural effusion. Repeated cultures of the serous colored fluid have failed to demonstrate any bacterial growth. The chest X ray is negative so far as any pulmonary parenchymal lesion is concerned. He has a positive tuberculin test, but no acid-fast bacilli have been found on several gastric analyses. A pleural biopsy has not been performed. Would you recommend tuberculous antibacterial therapy in this man, particularly in the face of the chest X-ray findings?

ANSWER: A large number, perhaps even a majority, of patients with tuberculous pleurisy with effusion will develop active tuberculosis in some part of the body within five years. In the great majority of cases, tuberculosis is the cause of so-called idiopathic pleurisy with effusion among patients possessing positive tuberculin tests. For this reason, in the case cited, the patient certainly deserves an antibacterial therapy regimen directed against tuberculosis. Such a regimen should ordinarily extend over at least a continuous 18-month period. Although isoniazid alone is probably adequate, some physicians prefer to combine its use with aminosalicylic acid. You relate that a pleural biopsy was not done. The diagnosis may often be made through use of that procedure when other diagnostic measures have failed. Therefore, utilization of that diagnostic technique should be seriously considered before initiating the program of chemotherapy.

The Viewing Box

THIS IS A nine-year-old male whose pertinent history began three days prior to his admission to Children's Hospital. At that time there was an abrupt onset of diarrhea and generalized crampy abdominal pain. This was followed the next morning by intermittent vomiting. Because of persistence of the vomiting and the diffuse abdominal pain, the patient was seen by his family physician who gave the child Thorazine, with abrupt cessation of vomiting. However, the patient continued to have diffuse abdominal pain, and on the day of his admission the pain became somewhat more severe and localized. Throughout this three-day history it was noted that the patient had a persistent temperature of around 101 degrees orally.

On physical examination, rebound tenderness was noted throughout the abdomen. Exquisite tenderness was noted in the retrocecal area.

Laboratory findings revealed a leukocyte count of 29,950 with 90 per cent neutrophils. The hemoglobin was 13.9 grams and the urine contained occasional red blood cells per high power field.

X-ray examination of the chest was negative (Figure 1). The abdominal film revealed a moderate reflex ileus and a 1-cm. laminated right pelvic calcification.

What is your diagnosis? (See next page.)

Fig. 1 — Supine abdomen taken on admission to hospital. It shows ileus and a 1-cm. laminated right pelvic calcification.

DIAGNOSIS: At surgery, an acute, gangrenous appendicitis with rupture and periappendiceal abscess was found. The appendix contained a 9×15 mm. coprolith, which is well shown on an x-ray of the specimen (Figure 2).

Fig. 2 — X-ray of removed appendix. Note bulbous distention distal to coprolith.

Coproliths

Coprolith is a word derived from the Greek, meaning "dung stone". In general it refers to a fecalith which contains sufficient calcium phosphate to make it radiopaque. Appendiceal calculi (or coproliths) are radiographically demonstrable in from four to fifteen percent of the patients with acute appendicitis. In the genesis of a coprolith, impairment of the normal fecal return from the appendix into the cecum results in the formation of an inspissated appendiceal fecalith. The combination of mechanical irritation by the fecalith and the bacterial activity produces a low grade catarrhal inflammation, resulting in formation of a large amount of mucus. The inorganic salts in the mucus (chiefly calcium phosphate) are precipitated on the surface of the fecalith, transforming it into a radiopaque coprolith. Repeated episodes result in lamination and enlargement of the coprolith with additional "inflammation" in the adjacent appendiceal wall.

Because of the variation in the position of the appendix, the coprolith may be found anywhere in the right abdomen, and rarely on the left side. However, in the vast majority of cases, it is found in the right lower quadrant, usually at the level of the sacroiliac joint or iliac crest. In most instances, it is laminated; occasionally it is faceted, especially when multiple stones are present. It is usually round or oval and commonly under 2 cm. in size. In approximately two thirds of reported cases, only a single stone is visualized.

Acute appendicitis is the most common abdominal disease requiring surgery, and it is estimated to be the cause of 17,000 deaths annually in the United States. Recognition of a coprolith may lead to an earlier diagnosis of acute appendicitis, particularly in those cases which are atypical or whose signs and symptoms suggest another condition.

Acute appendicitis is present in 90 percent of patients with coprolith formation, and in 50 percent of such cases perforation has already occurred. In many patients with coprolith formation, the history, physical and laboratory findings are atypical of appendicitis and the diagnosis may

COPROLITHS

not be suspected unless an abdominal film is taken. Therefore, while an abdominal film is unnecessary in clinically typical cases of appendicitis, it should be taken in any case of atypical abdominal pain. Radiological demonstration of a coprolith should prompt immediate exploration despite the atypicality of the signs and symptoms of acute appendicitis clinically.

Occasionally patients with coproliths and without symptoms are encountered. These patients almost invariably develop acute appendicitis subsequently; therefore in such patients, prophylactic appendectomy is probably indicated.

Conditions which can simulate coproliths include benign bone islands, ureteral and vesical calculi, calcified mesenteric nodes, phleboliths, radio-paque medication, gallstones, and calcified appendices epiploiae. While any of these can offer diagnostic difficulty, appropriate x-ray studies will usually differentiate.

A typical case of acute appendicitis with a coprolith is presented. In making the correct diagnosis and initiating prompt therapy in atypical cases, however, the recognition of a coprolith is important and can be made only by an abdominal film.

Buckle Up

Passing

Modern road design makes passing a safe and easy operation if motorists follow these few simple rules:

Stay in the right-hand lane (unless otherwise marked) until ready to pass.

Don't pass cars going over the speed limit or trying to prevent you from passing.

Signal well in advance. Make sure no one is in your blind spot (that area behind the left rear fender).

Sound horn when passing.

Take special care when passing trucks. Trucks may appear to be going more slowly than they are.

Check to see if drivers ahead or behind are going to pass. Check traffic conditions around you. Check side and rear view mirrors.

Stay in the passing lane until you can see the car you've passed in your rear view mirror. Signal before moving back into the right-hand lane.

Adjust speed to traffic flow. Avoid zig-zagging from lane to lane to pass other vehicles.

Here is my creed. I believe in one God, the creator of the Universe. That he governs it by his Providence. That he ought to be worshipped. That the most acceptable service we render to him is doing good to his other children. That the soul of man is immortal, and will be treated with justice in another life, respecting its conduct in this. These, I take to be the fundamental points in all religion. —

Benjamin Franklin 1706-1790

Tumor Conference

Tumor and Tuberculosis

AN APPRECIATION of the higher incidence of carcinoma of the lung in patients with tuberculosis has emerged in the last decade. A recent case pointed up this relationship and raised other problems in diagnosis and management which are worthy of comment.

Case Report

The patient was a 45-year-old barber and janitor who was admitted to the respiratory isolation ward on 10-1-64 with a fever and a cough after x-ray examination of his chest showed multiple nodular densities with cavitation in both upper lung fields. He was an alcohol addict. He had been treated in the outpatient department for mild diabetes managed by diet and oral hypoglycemic agents. He had smoked one to two packages of cigarettes a day for 30 years. In the ten years preceding admission he had been hospitalized or treated for "pneumonia" on eight occasions in various parts of the country.

The admission sputum cultures grew out typical *mycobacterium tuberculosis*. On subsequent testing these organisms were sensitive, *in vitro*, to para aminosalicylic acid, isoniazide and viomycin. The patient was intensively treated for six months in the hospital with isoniazide and para-aminosalicylic acid. He was discharged after marked resolution of the pulmonary infiltrates and after six sputum cultures showed

Fig. 1 — This chest film shows the right upper lobe mass, indicated by the arrow.

Fig. 2 — The upper arrow indicates the area of destruction of the second rib. The mass is slightly larger than on the film three weeks previously.

Continued

TUMOR CONFERENCE

no growth of *Mycobacterium*. He was followed with serial roentgenograms and cultures in the outpatient department while continuing on medications. One year after his original admission he was admitted for a second time because one of the follow-up cultures grew *M. tuberculosis*. Shortly after this second admission, he complained of mild right shoulder and chest pain. Admission chest films showed some increase in the infiltrates in the right apex.

The admission film is shown in Figure 1. In comparison to the films of the preceding two months there was no change in the nodular lesion in the right upper chest. During the next two to three weeks the patient complained of more chest pain and pain with motion of the right shoulder. Because of this, a chest film was taken (Figure 2) and destruction of the right second rib was noted. A planigram (Figure 3) illustrates the rib erosion better. Preoperative studies showed a hemoglobin of 12 gm., wbc. 9,700, with 47% PMNs, 34% lymphocytes, 4% monocytes, 14% eosinophils, and 1% basophils. VDRL was negative. BUN was 14 mgm.%. FBS was 126 mgm.%. A 2-hour p.c. blood sugar was 309 mgm.%. A BSP test had 4% retention at 45 minutes. Bence-Jones proteins were not present in the urine. One-second forced expiratory volume was 2.3 liters; 3-second forced expiratory volume was 3.5 liters. There were no significant findings on bronchoscopy. Scalene lymph node biopsy did not contain tumor in the nodes obtained.

Fig. 3 — This is a planigram showing the rib erosion between the two arrows.

On 4-11-66 a right thoracotomy was done. The tumor was found to be adherent to the second and third ribs. The spinal column, azygos vein, and vena cava were not involved. The right upper lobe was resected in continuity with the first, second, third and fourth ribs and transverse processes. Grossly, the tumor had not invaded locally beyond the chest wall. Examination of the specimen showed a well differentiated peripheral bronchogenic squamous cell carcinoma invading the chest wall. The hilar nodes were free of tumor but showed caseous necrosis. Postoperatively, the patient was continued on isoniazide and para-aminosalicylic acid. There were no operative complications. The shoulder pain did not recur. Unfortunately, two months postoperatively, severe left back pain occurred. X rays showed a destructive lesion in the left scapula. Local therapeutic x-ray treatment was started in hopes of giving pain relief. Within several weeks other metastases appeared in the dorsal and lumbar spine as well as the right scapula. The patient had increasing debilitation with wasting. He died four months postoperatively. Autopsy confirmed the presence of widespread metastatic squamous cell carcinoma.

Comment

Although this case could be dismissed as the simple chronicle of an unfortunate patient dying of uncontrolled bronchogenic carcinoma of the

lung, it does raise several interesting questions. First, is there any important relationship between carcinoma of the lung and pulmonary tuberculosis? In our hospital there appears to be more than a fortuitous relationship of the two diseases. Between 1947 and 1965 there were 1164 new cases of carcinoma of the lung admitted to the Minneapolis Veterans Hospital.¹ Of these, 43 patients (about 4%) had been treated or were under treatment for tuberculosis. Other authors, reviewing recent experience, have quoted an incidence of association of the two diseases varying from 2 to 9% in the United States² to as high as 31% in countries with high tuberculosis infections rates.³ Most of the studies supporting the idea that tuberculosis increases the likelihood of bronchogenic carcinoma have been in the last ten years since the introduction of effective antituberculosis agents. In the past, "tuberculosis was the disease of the young who did not live to see the cancer age."⁴ White, Beck and Pecora⁶ emphasized the changing age of the tuberculosis patient. In a New York State Sanatorium, in 1940, men over 45 years old represented only 5.9% of the population. By 1957, over 40% of their patients were men over 45 years old. It is only reasonable to assume that patients with advanced tuberculosis are surviving longer since the advent of antituberculosis drugs. Steinitz³ used the excellent disease registries for tuberculosis and cancer in Israel to get a better estimate of the risk of bronchogenic carcinoma occurring in patients with active or inactive tuberculosis. She made an extensive study of these patients who appeared in both registries. It was her conclusion that having tuberculosis increased the risk of developing bronchogenic carcinoma over that of the general population by a factor of five in males, and by a factor of ten in females. Incidentally, less than 2% of the women were smokers. In other series, where smokers are much more frequent, the additional effect of heavy smoking is not clear.

The evidence is fairly clear that the finding of *Mycobacterium* in the sputum of a patient with pulmonary disease should make the possibility of malignancy *more* rather than *less* suspect. A patient who has tuberculosis has a risk of developing carcinoma of the lung equal to that of a heavy smoker.³ In several series, the diagnosis of cancer was made in tuberculosis patients by the usual means. In 15 patients, Holden⁵ found gross tumor by bronchoscopy in four. Six of seven patients, who had sputum smears examined, had tumor cells present. One of eight patients had a positive scalene node biopsy.

In the case presented above, the occurrence of rib erosions pointed clearly to malignancy. Less blatant signs of possible cancer are: (1) Clearing of pulmonary infiltrates in one area of the lung during therapy while disease is progressing in another area; (2) X-ray evidence of progression of the disease with a persistently negative sputum; (3) Unilateral hilar enlargement; (4) Progressively enlarging nodular densities arising during treatment; (5) Persistent expiratory rhonchus. If diagnostic tests remain negative for tumor and strong suspicion of tumor is present, a diagnostic thoracotomy should be performed.

The site of bronchogenic carcinoma is not necessarily in physical relationship to the tuberculous infiltrates or old scar. White, Beck and Pecora found that the carcinoma occurred in the areas of previous tuberculosis in only one half of their cases.⁶

Continued

TUMOR CONFERENCE

The second question raised by the unhappy outcome in this patient was whether the extensive curative attempt was worth while in the face of chest-wall invasion. At the Minneapolis Veterans Hospital, in-continuity chest wall resection for tumor invasion has been done on 20 (6.5%) of 306 cases resected in a curative attempt between 1947 and 1965. Most of the cases were done in the past five years. Of those patients in whom there is a follow-up, six of 11 possible patients have survived for one year, and one of five possible patients has survived from those patients done at least three years ago. It would seem from this brief experience that the attempt is worthwhile. This is confirmed by Grillo⁷ who had three of 19 patients having in-continuity lung and chest wall resections surviving four to 14 years. The results are similar to the series by Gronqvist, Clagett, and McDonald,⁸ who had four of 16 possible patients surviving one year to six and a half years.

Grillo's findings further emphasized the necessity of chest wall resection rather than extrapleural dissection.⁷ None of his 14 patients treated by extrapleural resection survived over four years compared to the three survivors with chest wall resections.

As a third and final point, it should be emphasized that chest wall and/or shoulder pain with any pulmonary lesion is highly suspicious of malignancy⁹ and is the most common symptom of chest wall involvement.⁷ Clagett found this symptom in 14 of his 16 resected cases.⁸

Medical Seminar

Tick Paralysis

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

TICK PARALYSIS is a rapidly fatal but easily cured disease of man and animal, produced by the bite of a tick and characterized by an ascending symmetric, flaccid paralysis. This disease is distinct from the tick-borne rickettsial diseases.

William Hovell¹ in 1824 was the first to report this disease when, while travelling through Australia, he noted that a small insect called a tick "buries itself in the flesh and would in time destroy either man or beast if not removed in time." Initially, tick paralysis was a problem only for sheep herders, who annually lost many of their sheep to this condition. (Numerous ticks were found fastened to the backs of the sheep.) The occurrence of tick paralysis in North America was not noted in the literature until 1912 when Todd² reported cases involving persons from British Columbia; these cases dated back to 1898. Since that time additional reports of tick paralysis in both man and animal have appeared in the literature, describing further the clinical and the pathophysiologic aspects of this disease.

Incidence

As of 1965, about 100 cases have been reported in the United States. The mortality rate in these cases is about 10%.³ In Canada, the 250 cases reported to date have had a mortality rate of 11.2%.³

Although seen in adults, the disease is more common in infants and small children; twice as many girls as boys are involved. The higher incidence of girls is attributed to

their having longer hair which provides an optimal situation for the tick to remain implanted and undetected.

Tick paralysis has been seen in 15 of the 50 states but is common only in states west of the Rocky Mountains (Washington, Oregon, Idaho, Montana, Colorado, and Wyoming) and in British Columbia and Alberta, Canada. In Australia the regions with the highest incidence are situated in two narrow strips along both eastern and western coasts.

The Vector

The tick *Dermacentor andersoni* is largely responsible for the cases in the Pacific Northwest; the *Dermacentor variabilis*, for those from eastern and southern United States; the *Amblyomma americanum*, for those from southern United States; and *Ixodes holocyclus*, for those from Australia. In the state of Minnesota, *D. variabilis* seems to be a prominent species.⁴ However, there are no reports of paralysis in Minnesota being caused by this species. Briefly, the wood tick passes through four stages of development: egg, larva, nymph, and adult.

Egg, Larva Stage

The eggs are laid in masses in thick clumps of grass. After they are hatched, the larval forms attach to host animals (usually small rodents), become engorged with blood, and drop to the ground. On the ground they shed their skin and become nymphs.

Continued

The Nymph and Adult Stage

The nymphs then attach to another host, again engorge themselves with blood, and in several days drop to the ground, molt, and become adults. The adults of both sexes are next brushed from the grass or shrubs onto a passing host (man or animal).

The Host

They may immediately fasten themselves via their mouthparts to the host and, as is more commonly seen, migrate from the lower extremities upward toward the head. This migration has given the false impression that the ticks have fallen from trees.

In choosing its final point of attachment, the tick favors a protected region of the body. It attaches to the scalp or neck area in 63%⁵ of the cases and in the remainder, to areas such as the inguinal and axillary regions, the vulva, and the umbilicus. Once attached, the ticks mate or engorge themselves with blood from the host or do both. Complete engorgement requires six to 10 days, during which time eggs develop in the female and both male and female may increase in weight from 1 to 450 mg. Maximal engorgement occurs between the third and the fifth day. The adults then drop off, and the female lays her eggs and dies.

The Neurotoxin

Production and injection of the neurotoxin responsible for tick paralysis requires at least four to six days of engorgement. Such a long latent period between attachment and paralysis is extremely important epidemiologically, as a patient may have the disease and be well outside the endemic area. Although the majority of cases are caused by the female tick, a few cases⁶ attributable to males have been reported recently.

In general, ticks attach in early spring and summer. In temperate climates they are rarely seen after August 1.

Clinical Aspects

The classic clinical picture is seen in a child or infant and, as stated previously, more commonly in a girl.

Non-specific Complaints

Twelve to 24 hours prior to paralysis, the patient may manifest vague, nonspecific complaints such as irritability, fatigue, paresthesia in the lower extremities, and fleeting muscular pains.

Weakness

The child often appears well when put to bed in the evening, but on arising in the morning is noted to have weakness in the lower extremities and a prominent ataxia in all upper and lower extremities. It is uncertain whether this ataxia is cerebellar in origin or secondary to the weakness per se.

Flaccid Paralysis

During the next few hours, the weakness changes to a flaccid paralysis. Twelve to 48 hours later, this paralysis progresses from the lower extremities to the upper ones in a rather symmetric fashion and, if the tick is not found and removed, the progression continues to eventually involve the cranial nerves in the same ascending symmetric manner. There may be sternocleidomastoid paralysis, lingual paralysis, dysphagia, dysarthria, facial paralysis, and ocular weakness.

Respiratory Paralysis

Eventually the patient dies of respiratory paralysis unless the causative tick is found. Respiratory paralysis may occur suddenly and unexpectedly, and its threat must always be anticipated. Myoclonic twitches and choreiform movements have been reported to occur during the earlier stages. Convulsions may occur terminally and are believed to be secondary to hypoxia.

Physical Findings

On examination, the prominent finding is a flaccid paralysis of the extremities associated with decreased or absent deep-tendon reflexes. Early in the course there may be a positive Romberg sign along with dyssynergia and dysmetria in the upper extremities. Sensory signs usually are absent, although sensory symptoms such as pain and par-

esthesia are frequently noted. Evidence of cranial-nerve palsies such as ptosis, as well as facial and palatal weakness, may be present. The general sensorium and mood of the patient characteristically remain normal, although apprehension often appears terminally. Temperature and pulse also remain normal unless bulbar involvement occurs or unless an infectious process is also present.

Unusual instances of localized weakness occur. Examples of these are facial weakness from a tick in the external auditory canal, frontalis and orbiculares oculi paralysis from a tick on the forehead, leg weakness secondary to a tick on the genitalia, and brachial-plexus palsy associated with a tick over the brachial plexus.

Laboratory Findings

The cerebrospinal fluid is characteristically normal, although occasionally the pressure may be slightly elevated; the serum protein may reach 50 mg. per 100 ml., and a slight pleocytosis may exist. Results of routine blood studies are normal in most cases.

Prognosis

The course of tick paralysis depends entirely on two factors: when the tick is found and whether it is removed. If the tick is removed early, there may be no symptoms at all. If it is removed during the illness and prior to bulbar weakness, improvement invariably occurs within hours and ability to walk returns 12 hours to two days later. Complete recovery by one week is the rule. If the tick is allowed to remain until bulbar symptoms have begun, death will often occur from respiratory paralysis despite heroic measures.

Differential Diagnosis

Polio is the most frequent consideration in the differential diagnosis. However, there are several features that distinguish polio from tick paralysis: In contrast to polio, patients with tick paralysis have no fever, no meningeal signs, no muscle spasms, and

a normal spinal fluid. Guillain-Barré syndrome, tumor of the cord, and syringomyelia* can be differentiated because of the normal results of the sensory examination and the normal spinal fluid seen in tick paralysis.

Pathologic Features

In general, pathologic studies are unrevealing. In one case⁷ in which the diagnosis of tick paralysis was doubtful, the patient had diffuse cerebral engorgement and round-cell infiltration. In the experimental animal, pathologic alterations are inconsistently seen and, when present, include congestion in the brain as well as in the anterior and posterior horn grey matter of the spinal cord.

Neurotoxin

Origin

Experimentally, paralytic symptoms have been produced only with gravid females or ripening eggs. Emulsions of salivary glands from the female tick injected subcutaneously into mice produce paralysis, but do so in a rather inconsistent manner. Thus, it is doubtful whether salivary glands alone are responsible for the disease. Emulsions of the eggs of the tick also produce the disease in experimental animals and apparently with greater frequency than do emulsions of either the salivary gland or the whole tick. At present, both the salivary glands and the eggs are believed to contain the neurotoxin. The neurotoxin apparently is injected into the host via the salivary-gland secretions of the tick.

Site of Action

The site of action of the neurotoxin has been described recently by Murnaghan.^{8,9} Neurophysiologic studies were carried out on dogs paralyzed by *D. andersoni*. The anterior tibial muscle was isolated for study and was noted to contract normally on direct stimulation but not to contract when stimulated via the peroneal nerve. Subsequent stimulation of the ventral root produced a normal action potential at several sites along the nerve, thus indicating that

*See Test Your Word Score Page 363.

Continued

those parts of the nerve were normal. Repetitive stimulation of the nerve indicated that the paralysis was unlike that noted with neuromuscular blocking agents but was more suggestive of an abnormality in the tiny terminals of the nerve. Subsequent studies on the same preparation revealed no abnormality of acetylcholine synthesis or storage but showed a decreased release of acetylcholine from the nerve terminal after stimulation. Thus, Murnaghan^{8,9} concluded that the site of block was at the tiny, pre-synaptic terminal fibers of the somatic motor nerves.

Treatment

The first step in successful treatment is the clinician's suspicion of this disease in instances of ascending paralysis that occur between February and August. A careful search for the tick must be made, the clinician taking care to examine the preferred sites of attachment. Once located, the tick must be carefully and completely removed, because only after the head parts are removed will the symptoms clear. Several

methods of removal have been suggested: (1) A volatile substance such as ether, gasoline, or kerosene may be spread over the tick; (2) a lighted cigarette or match may be placed near the tick; (3) petrolatum may be used to cover the tick; and (4) adhesive tape may be placed over the tick and pulled gently.

With each of these measures, five to 10 minutes are required for the tick to loosen its grip. Once the tick is removed, the wound should be treated with a germicidal agent. Because infection can result, crushing the tick between the fingers must not be attempted. To kill the tick, kerosene or turpentine should be used.

Anti-tick dog serum has been tried in animals with moderate success. However, use of such sera in humans has resulted in severe urticarial reactions.

In cases of bulbar paralysis, adequate support of both respiration and blood pressure is important.

Narcotics should be avoided in view of the threat of respiratory depression.

Every living body exhibits in a fourfold form the process of equilibration; from moment to moment in the balancing of mechanical forces; from hour to hour in the balancing of functions; from year to year in the changes of state that compensate changes of conditions; and, finally, in the complete arrest of vital movements at death.

— Herbert Spencer

Clinical Path Conference

Unusual Renal Complications in Diabetes Mellitus

A 69-year-old white male diabetic, was admitted to Hennepin County General Hospital because of fever and lethargy.

Eighteen years previously diabetes mellitus had been detected. Fifteen years previously insulin PZI, 15 units, regular 10 units) in addition to diet was necessary for adequate diabetic control. Routine laboratory tests at this time were normal.

The patient returned 14 years before his final admission because of nocturia (4×) and slowing of the urinary stream. Benign prostatic hypertrophy (graded 2+) was noted. Residual urine was 75 cc. He failed to return for laboratory examinations.

Seven years before his final admission, subtotal gastrectomy was done, because of gastrointestinal hemorrhage from a duodenal ulcer.

Six years before his final admission gangrene of the left foot necessitated supracondylar amputation. His diabetes was well controlled with diet and insulin (NPH, 25 units). Urinalysis showed trace albumin, occasional red blood cells and 8 to 10 white blood cells per high powered field. Specific gravity was 1.024.

Five days before his final admission he was sent to the outpatient department by his nursing home because of lethargy and refusal to eat or take medicines. Complaints at this time included increased urinary frequency (every hour while awake), nocturia (5×), hesitancy and decreased force of the urinary stream. For reasons that are not clear, the patient had been digitalized on a maintenance dose of digitoxin .2 mg. per day, by his private physician. His insulin requirement had increased to 65 units of NPH per day. No insulin had been taken for three days prior to this visit. The blood pressure was 120 mm. mercury systolic, 80 diastolic, the pulse 100, temperature 98 degrees and body weight 140 pounds. Findings included bilateral cataracts, benign prostatic hypertrophy (graded 2+), a supracondylar amputation of the left lower extremity and absent popliteal and pedal pulses in the right lower extremity.

The hemoglobin was 14.7 gm. %, white blood count 11,850, blood urea nitrogen 24 mgm. %. A fasting blood sugar was 278 mgm. %. Electrocardiogram showed a sinus tachycardia with left axis deviation, first degree heart block and depressed ST segments. The urine was acid with specific gravity 1.024, albumin 1+, sugar negative and acetone trace. The urinary sediment showed 4+ pus cells per high powered field.

The bladder was catheterized with difficulty; 300 cc. of cloudy residual urine was obtained. This urine was cultured. The patient was to return in one week for prostatic surgery.

Because of increasing lethargy and fever he was admitted three days later. The temperature was 105 degrees rectally. Respirations were 50, pulse 148 and regular and blood pressure 150 mm. mercury systolic, 50 diastolic. The right pupil was slightly larger than the left. Bilateral cataracts precluded adequate fundusoscopic examination. The neck was not rigid but some resistance to flexion was present.

A few crackling rales were audible over the base of the right lung posteriorly. The left border of cardiac dullness was percussed in the 5th intercostal space 10 cm. from the mid-sternal line. Neurologic examination was normal. No response to pain was obtained.

Bowel sounds were decreased. The dome of the bladder was palpated at the level of the umbilicus. Catheterization yielded 1,500 cc. of cloudy urine.

Continued

The hemoglobin was 13.3 gm. %, white blood count 22,100, differential count 96% neutrophils, 3% lymphocytes and 1% monocytes. Urinalysis showed specific gravity 1.019, 2+ albumin, 3+ sugar, and trace acetone. Urinary sediment was packed with white blood cells and had four red blood cells per high powered field. The blood sugar was 333 mgm. %.

The chest x-ray was normal. Blood pH was 7.42, pCO_2 was 34 mm. of mercury. The serum sodium was 136 meq./L. potassium 3.6 meq./L. chloride 99 meq./L. and CO_2 combining power 22 meq./L. The electrocardiogram was unchanged except for increased S-T segment depression.

Staphylococcus aureus had grown from the urine obtained in the outpatient department five days previously. After blood cultures were obtained, the patient was treated with penicillin (6 million units per day) and tetracycline (4 gm. per day) intravenously. Within 24 hours the temperature had decreased to 99 degrees rectally.

Staphylococcus aureus had grown from the blood on the third hospital day. Organisms from the blood and urine had identical antibiotic sensitivities. Procaine penicillin, 600,000 intramuscularly every 12 hours, and tetracycline, 500 mgm. by mouth, were substituted for the intravenous medications.

The patient became more responsive. He was able to sit up and eat. Regular insulin, 10 to 30 units per day, was used to control glycosuria. The temperature varied between 99 and 101 degrees rectally over the next four days.

On the sixth hospital day the patient became more lethargic, temperature was 103.2 rectally, pulse 140, respirations 30. Examination was otherwise unchanged. A lumbar puncture showed clear fluid. Spinal fluid pressure was 122 mm. of spinal fluid. Proteins and cells were normal.

The blood sugar was 384 mgm. %. Urinalysis showed specific gravity 1.024, trace albumin, 4+ sugar and was acid. The sediment contained 65 red blood cells and 6 white blood cells per high powered field. Blood pH was 7.41 and pCO_2 29. The serum sodium was 146 meq./L, potassium 5.6 meq./L, chloride 111 meq./L, and CO_2 combining power 17 meq./L.

The patient died the eighth hospital day.

Discussion

Dr. William Torp:*

This man's disease had progressed to the point where he had multiple diabetic complications, i.e., bilateral cataracts, renal disease and peripheral vascular involvement which necessitated amputation of his lower extremity. I would predict that retinal changes were present but could not be detected because of cataracts. One gains the impression from the protocol that we were dealing with a rather unreliable patient who failed to keep his clinic appointments and probably failed to follow instructions regarding regulation of his diabetes. Evidently diabetic control was not difficult to maintain during his previous hospitalizations. I searched for an obscure diagnosis in this patient but none was evident, and I feel that he probably died from an acute complication of his diabetic state. I should like to discuss this case in the order of the events that occurred, pointing up either their merits or the demerits.

This patient's diabetic control was probably never optimal since glycosuria was generally present on his hospital admissions. This, coupled with his failure to return to clinic, would suggest that this man took his insulin quite sporadically. The only insulin regulation that we are aware of was when he was hospitalized and was relatively easily controlled. He was not a good clinic attender. While there is some discussion about how closely a maturity onset diabetic should be controlled, the general feeling is that blood sugars should be kept as near normal as possible with the objectives of avoiding hypoglycemic episodes and controlling hyperlipemia. Patient reliability is an important factor in the adequacy of diabetic control. With many patients control is satisfactory when they are spilling a minimal amount of sugar in their urine and

*Resident in Internal Medicine, Hennepin County General Hospital.

have a minimal hyperglycemia. We would rather control them in this fashion than chance a hypoglycemic reaction.

This patient's first indication that he was going to be a problem occurred fourteen years prior to his current admission when benign prostatic hypertrophy was noted. Failure to keep his clinic appointments resulted in an incomplete evaluation at that time.

Seven years prior to his admission the patient had a subtotal gastrectomy. We must assume that the diabetes was adequately controlled and that urinary tract symptoms were minimal during hospitalization. Retinal changes are not mentioned. The blood pressure is not recorded.

Six years prior to his current admission an above-the-knee amputation was necessary, and we might assume at this time that his vascular disease was becoming evident. Urinalysis now shows some renal involvement with albuminuria and red and white cells in the sediment.

This takes us to our final contact with the patient, and I think we can assume that he has widespread vascular disease at this time. We have now an ill white male who presents with two danger signs, the complaints of anorexia and lethargy. These are often the first indications we have that the patient may be acidotic, but we know that maturity onset diabetes seldom develop keto acidosis. According to the protocol the patient had had no insulin for three days prior to his being seen here. At this time he is using 65 units of NPN insulin, but we have no information about his diabetic control. He is again showing signs and symptoms of urinary outlet obstruction, and we must be overly suspicious of urinary tract infection. An estimated 20 to 40% of diabetics will develop pyelonephritis.

It is also important to note that the patient is now taking digitoxin — 0.2 milligrams per day. He is 69 years old, weighs 140 pounds and has renal impairment. I therefore think it is quite likely that this dose of digitoxin for this particular patient is much too high. According to Friedberg this is the upper limit for a maintenance dose, and it is at this level that we might well expect complications. The reasons for originally digitalizing this patient are not stated. The tachycardia and first degree heart block on the electrocardiogram, in addition to the depression of the ST segments, would add to our suspicions of digitalis intoxication. Digitalis intoxication might also cause symptoms of anorexia and lethargy. We do not know whether his digitalis was stopped, or whether he was treated for digitalis intoxication.

Laboratory investigation indicates that the patient is not acidotic. The diabetic with marked renal involvement may have a high threshold for glucose excretion in the urine, and therefore the urine sugars may not be nearly as helpful as in one who has relatively normal renal function. Urinalysis indicates a probable urinary tract infection, and again there were symptoms of probable bladder outlet obstruction. A note is made that the patient was catheterized with difficulty and a significant residual volume obtained. In an elderly patient, particularly if that patient is diabetic, one can almost predict that he is going to get into trouble with his urinary tract following such a procedure.

We do not know the exact onset of this man's difficulties, but from his continuing course one might expect a gram-negative bacteremia, and one

Continued

could easily justify starting the patient on some therapy at the time of the difficult catheterization. The antibiotics should be started after obtaining suitable urine specimens for culture. At any rate, this man was dismissed from, or sent home from, the outpatient clinic without any treatment, whereas hospitalization was indicated.

He returns three days later quite toxic and febrile. I think most of us would assume on this admission that the man had a gram-negative bacteremia. However, we are fortunate here in that the cultures obtained in the outpatient department three days previously had returned, and it is a little surprising to find that the urine grew *Staphylococcus aureus*. However, diabetics are more prone to staph infections than nondiabetics and they do not tolerate them as well. The rales heard in his chest might indicate a pneumonia, and it must be remembered that patients who present in a dehydrated state may have a relative sparsity of pulmonary findings. On re-hydration these pulmonary findings may be quite prominent. The chest x-ray may behave similarly.

I think we should also note that for the first time the patient is observed to have anisocoria. We do not know whether this is a normal finding for this patient. Difference in pupil size of approximately a millimeter may be considered normal. If the anisocoria were prominent we might wonder about some previous head trauma, particularly a subdural hematoma, which seems to occur with unusual frequency in diabetics. The clinical course is certainly compatible with such a diagnosis. This should be followed up with a lumbar puncture and skull x-rays, and should anything suspicious be noted angiography might be indicated.

With antibiotic therapy the patient appeared to improve, he was able to sit up and eat. This still does not exclude the diagnosis of subdural hematoma. These patients will not infrequently seem to be a little better before they get worse. The anisocoria might also reflect a complication of the diabetes. Third nerve neuropathies are seen in approximately 4% of the diabetic population. The anisocoria in the diabetic may also be transient, disappearing within five to six weeks.

The repeat electrocardiogram shows no change from the previous tracing. However, the digitoxin had been stopped only three days previously, and it may take longer than this before evidence of toxicity disappears, particularly in a patient with renal impairment. Again, we have no laboratory evidence of acidosis. The antibiotics used were penicillin—6,000,000 units per day and four grams of tetracycline per day. Apparently both of these were given intravenously. The dosage of penicillin for a susceptible organism in a patient with a bacteremia seems low. Diabetics in particular do not handle staphylococcal infections well. The dosage of tetracycline on the other hand is much too high, especially in a patient with renal insufficiency. The intravenous dose of tetracycline per day should be limited to less than one gram, since complications of pancreatitis, fatty liver and renal damage have been reported, particularly in patients with some degree of renal insufficiency. After criticizing the selection and dosage used for antibiotic therapy, we find that the patient gets better. The blood cultures return, showing *Staphylococcus aureus* with the same sensitivities as the organism that was cultured from the urine. A sputum culture is not reported. The infection is now treated by decreasing the amount of penicillin and

tetracycline; the penicillin being given intravenously and the tetracycline orally. Now, even after we have a documented staphylococcal bacteremia, we still are not treating the patient adequately.

This patient should be receiving massive doses of penicillin. We must, however, always bear in mind that there is about a milliequivalent of potassium per million units of penicillin and this must be considered in our electrolyte therapy — especially with renal impairment. On the sixth hospital day the patient became quite toxic. An L.P. at this time was negative. While diabetics are particularly prone to fungal infections, such as torulosis, I think we have enough disease in this patient to explain the cause of his increasing symptoms and his death.

We now note an increase in the number of red blood cells in the urinary sediment. I presume that nothing else was evident on microscopic examination although one might expect casts and white blood counts.

Summary

We have a diabetic with rather widespread vascular disease, some renal involvement, a urinary tract infection, bacteremia, perhaps a pneumonia and probable digitalis intoxication. Urine output was maintained right up to the time of death, although in the two to three days prior to death it had decreased somewhat. This decrease amounted to approximately 1800 cc. per twenty-four hours. However, the patient was still excreting between 1500 and 2000 cc. of urine per day.

We do not have follow-up chest x-rays or follow-up electrocardiograms, and I think we still have to keep the possibility of a subdural hematoma in mind. We know that the man had a staphylococcal bacteremia. We can assume that he had a staphylococcal pyelonephritis. We might suspect that he has pneumonia and also suspect that on pathologic examination he will show marked renal changes. We might also suspect that he may have renal papillary necrosis. Although the absence of oliguria is somewhat against this diagnosis, this may occur late in the course of events. In a report in the *Journal of Urology* in 1957, of the 211 cases of renal papillary necrosis reported up to 1955, 129 were in diabetic patients. An arrhythmia secondary to digitalis intoxication cannot be excluded.

Dr. A. L. Schultz:*

Why the patient with maturity onset diabetes can withstand infection and multiple types of stress without becoming acidotic is not completely understood. I think the urinary tract findings are more compatible with a pyelonephritis than with a diabetic nephropathy. The nephrosclerotic type of diabetic nephropathy may result in a nephrotic syndrome. The diabetic is particularly prone to develop urinary tract infections and also papillary necrosis. Those that develop papillary necrosis slough out their kidneys and die in a matter of days. They develop renal failure and high fevers; examination of the urinary sediment may be diagnostic. The possibility of a renal abscess that is amenable to surgery should also be considered. Further urinary tract investigation is warranted if obstructive uropathy is strongly suspected. However, there is always the danger

*Head, Department of Internal Medicine, Hennepin County General Hospital.

Continued

of precipitating bacteremia in the man who has co-existent pyelonephritis and urinary tract manipulation.

Pathology

Dr. John Crosson:*

At autopsy the previously mentioned AK amputation of the left leg was observed. In addition the patient had adhesive pleuritis involving both lungs and also pericardial adhesions. In addition, he also had definite evidence of arteriosclerotic heart disease with the presence of an old sub-endocardial myocardial infarction. There was no evidence of an acute myocardial infarction. A bronchopneumonia was also present. Examination of the kidneys showed definite evidence of papillary necrosis, involving the

Fig. 1 — Gross picture of kidney showing papillary necrosis.

Fig 2 — Microscopic picture showing sharp demarcation between viable kidney and papillary necrosis ($\times 43$).

Fig. 3 — Acute pyelonephritis with clumps of bacteria in the center ($\times 43$).

*Resident in Pathology, Hennepin County General Hospital.

majority of the renal papillae. The necrotic papillae are sharply demarcated from the surrounding viable renal tissue. This sharp demarcation is evident both grossly and microscopically. In addition, one can see the shadows of the normal architecture maintained in the necrotic area. In association with the papillary necrosis this man had an extensive, acute pyelonephritis. Several clumps of bacteria are noted in the region of the inflammatory reaction. There was no evidence of diabetic glomerulosclerosis. Extensive arteriolar vascular disease is demonstrated by the hyalinization of the arterioles. Microscopic splenic infarcts were also present. In addition, the pancreas showed islet cell hyalinization. This man was a prime candidate for papillary necrosis. Besides being a diabetic, he also had an acute urinary tract infection with a relatively unusual organism, *Staphylococcus aureus*. In patients who develop papillary necrosis, however, this is a relatively common organism. Associated pyelonephritis is seen in practically 100% of patients with papillary necrosis.

I should like to discuss the clinical situations which should lead one to suspect papillary necrosis. In diabetics who show evidence of sepsis and urinary tract infection, this condition should be considered. Diabetics with the rapid onset of coma and a rapidly rising BUN might also have papillary necrosis.

The third large group encompasses diabetics with low-grade pyelonephritis who become acutely worse with the rapid onset of coma and deterioration. A fourth group, although relatively rare, is quite interesting. These are the people with renal colic secondary to the sloughed papillae. This presumably is also the reason for the hematuria that is frequently seen. Finally, patients with diabetic acidosis, whose acidosis is corrected chemically, but who still do not wake up, should be suspected of having papillary necrosis. As far as I know, tetracycline has not been associated with papillary necrosis.

William Torp, M.D.*

*Resident Internal Medicine.

Frontier Doctors' Self-Service

When illness struck the doctor, he was usually hundreds of miles from medical assistance and had to cure himself. Dr. M. F. Honan was a Bellevue graduate who practiced in La Grande, Oregon. One day he suffered terrible abdominal pains, diagnosed his condition as appendicitis, and operated on himself. He died under his own knife. He learned too late that he suffered not from appendicitis, but from an infected gall bladder with gallstones. Dr. George W. Mason of Klamath Falls, Oregon, proved more successful at self-surgery. As he was riding back to town on the California Road after tending to an injured freighter, his buggy wheel dropped into a muddy rut. The doctor was thrown from the seat so that his leg caught in the spokes of the wheel. The frightened horses bolted, and the doctor's leg was almost twisted off above the knee before he could bring the team to a halt. Knowing that only an immediate amputation could save his life, he cut off his limb and bandaged the stump with a silk muffler.

P·B·SAL·C

NON-HORMONAL ANTI-ARTHRITIC

Helps keep arthritic patients active

P-B-SAL-C is a dependable, effective salicylate formula for relief of pain due to rheumatoid arthritis, bursitis and fibrositis.

Its formula consists of a combination of sodium salicylate, para-aminobenzoic acid and ascorbic acid. This special combination provides higher, longer-lasting analgesic levels compared with salicylates alone. Each P-B-SAL-C Tablet is enteric coated to delay disintegration until it reaches the small intestine.

P-B-SAL-C, low in cost to your arthritic patients, will help keep them active.

FORMULA

Each enteric-coated P-B-SAL-C Tablet contains sodium salicylate 0.3 Gm., para-aminobenzoic acid 0.3 Gm., ascorbic acid 50.0 mg.

CONTRAINDICATIONS

Renal damage, salicylate sensitivity or in conjunction with sulfonamide therapy.

DOSAGE

Take 2 tablets four or more times daily.

ULMER

THE ULMER PHARMACAL CO.

1400 Harmon Place, Minneapolis, Minn. 55403

Diagnostics

The Diagnosis of Multiple Sclerosis*

IT IS NOT unusual in a neurological clinic to see three patients in succession with histories such as these. A lady of sixty-three years may be referred with the history that six months earlier she had suddenly developed a "numbness," a "tingling, itchy" feeling of her right antero-lateral thigh. At the onset she had consulted her physician who listened carefully and then mentioned several diagnostic possibilities, among them "something like multiple sclerosis." Over the next six months the complaint continued without change, but the lady became irritable, insomniac, anorexic and quite convinced that she was "dying of multiple sclerosis." The fact that she had a traumatic neuritis of the lateral femoral nerve (meralgia paraesthetica), a perfectly benign process, was "life saving" to her, but it did little to alleviate the six months of unnecessary anxiety.

The second patient may be a forty-two-year-old minister who awakened seven days earlier unable to close his left eye or move the left side of his face. The day after his facial trouble he became very unsteady, suffered vertigo and nausea and was unable to do his usual work. His physician was consulted at his office and both "multiple sclerosis" and "stroke" were mentioned in the differential diagnosis with less than a quieting effect on the patient. The diagnosis of geniculated herpes (Ramsey Hunt) was the accurate one and had a much less malignant connotation to the patient. He also was fortunate enough to have had a complete recovery of the facial paralysis during the following ten days.

The third patient may be an eighteen-year-old college freshman who described her trouble as being an "odd sensation of the left side of her body." The difficulty had developed over the Christmas holidays of her senior year in high school and had lasted for about three weeks. During the same period she had difficulty reading; the print of a book would "look double", especially when she was tired. Both complaints had disappeared shortly after she returned to school. In May, during preparation for the final examinations for her freshman college year, she again noticed that her left side was "different", "didn't want to work just right" and "felt numb." She consulted her physician and was told it was her "nerves" and that it would "probably be better after the examinations." This young lady showed dysconjugated movements of her eyes, a mild left sided incoordination and bilaterally positive toe signs. She had multiple sclerosis.

These three patients were a common clinical experience. The errors in the "making" and "not making" of the diagnosis of multiple sclerosis are the most numerous made in neurology. Much of the difficulty arises from the fact that since it has long been taught that the variability of this disease is quite unlimited, it is included in the differential diagnosis for any pathological involvement of the central nervous system. The difficulty is compounded by the wide-spread and

*Presented at the Black Hills Medical Seminar, August 5, 1966.

Continued

morbid lay publicity given multiple sclerosis in an effort to raise charity donations. The disease has a malignant connotation to the patient if he is erroneously told that he "has" or "might have" difficulty.

The diagnosis of multiple sclerosis can be very subtle and difficult, but usually it is not. The vast majority of cases behave much the same, and a few general rules can assure accurate diagnosis of at least seventy-five percent. It must be remembered that this is a disorder quite peculiar to the young, the initial lesion of the nervous system commonly occurs before the thirty-fifth year. A neurological lesion which presents in old age, with absolutely no previous central nerve system difficulty is not multiple sclerosis. The lesions of this disorder occur rather acutely over days, weeks or months, but once developed they do not remain constant in the early phase. The lesions improve and the symptom-sign complex of the patient remisses or becomes markedly better. This disease never produces only one lesion for long; a neurological examination always shows more than one site of pathological change. The sites that usually are involved produce dysfunction in the corticospinal system with variations of spastic paresis, the cerebellar system with incoordination, the cranial nerves with scotomas, oculomotor dysfunction and vertigo in the sensory system, especially the dorsal columns. These general rules must be adhered to, and unless a patient satisfies all three criteria: (1) onset before the age of thirty-five years, (2) a definite course of remission and exacerbations, and (3) more than one focus of pathology within the central nervous system, a diagnosis of multiple sclerosis should not be made and should certainly not be suggested to the patient.

Further certainty in establishing an accurate diagnosis of multiple sclerosis can be assured by being aware of symptoms which it seldom or never manifests. This disorder never starts after the age of forty-five, and it never involves only one site, as its name indicates. The lesion never continues to progress slowly; it invariably improves, with some degree of remission. The disease does not produce increased intracranial pressure or papilledema, nor does it produce paroxysmal phenomena of a seizure or convulsive type. The demyelinating lesions are central and do not produce a mononeuritis. If your patient shows these symptoms multiple sclerosis is not the correct diagnosis of his malady.

These few simple rules would have avoided the errors made in each of the three cases cited; likewise, they are good rules to follow in the diagnosis of central nervous system involvement.

St. Luke's Hospital Seminar

St. Luke's Hospital, St. Paul, is presenting a seminar entitled "Clinical Aspects of Hematology" on April 27, 1967, starting at 1:30 p.m., in the St. Luke's Hospital auditorium. The featured speaker will be Dr. A. J. Quick of Marquette University Medical School. Contact: C. E. Turbak, M.D. at St. Luke's Hospital.

Bacteremia Due to Gram-Negative Bacilli

Some Current Concepts of Therapy. Part I.*

FINLAND AND his associates,¹ McCabe and Jackson,² and members of our group³⁻⁶ have described the rate of bacteremia due to gram-negative bacilli as increasing threefold to fivefold in recent years. This presentation attempts to review the subject, with emphasis on some current concepts of its management. Such specific diseases as brucellosis, tularemia, and typhoid fever are not considered herein.

Causative Microorganisms

Only those cases in which two or more positive blood cultures were obtained and in which clinical examination showed true bacteremia have been included in our investigations.³⁻⁶ In our experience, *Escherichia coli* cause about one half of these infections; *E. coli* and *Klebsiella-Aerobacter* organisms, together, are causative in two thirds. Recently, *Pseudomonas* has displaced *Proteus* as the third most common pathogen. *Proteus* organisms cause bacteremia about twice as often as *Bacteroides*. Less common pathogens include *Paracolobactrum*, *Achromobacter*, *Salmonella*, *Shigella*, and *Alcaligenes*.

Pseudomonas organisms, although normal bowel inhabitants, are widely distributed in nature and are found in water, on skin surfaces, and in the air, giving them access to wounds, drugs, and medical instruments. Ordinarily, *Pseudomonas* organisms have little talent for sustained invasion, but when host defenses are incompletely developed, as in infants, or when defenses are weakened, as in debilitated adults, they can cause serious infections. The frequency of *Pseudomonas* infections may partly reflect the organisms' resistance to most antimicrobial

agents, allowing their emergence as predominating microbes when other bacteria are eradicated. Also, aging of the population, prolongation of life in patients with weakened defenses, and predisposing medical procedures may be contributing factors.

Bacteroides are anaerobic bacilli inhabiting such areas as the nasopharynx, bowel, and female genital tract. To detect *Bacteroides* bacteremia, all blood drawn for cultures should be inoculated into anaerobic media, such as deep tubes of dextrose brain broth. In about one third of patients having *Bacteroides* bacteremia, the bacilli are identified within 48 hours after inoculation of cultures, but in two thirds, incubation times range from 5 to 20 days. In about one fifth of patients having *Bacteroides* bacteremia, additional organisms, usually streptococci, are isolated simultaneously.

Age and Sex of Patients

In our experience, twice as many men as women have bacteremia of this type. More than 75% of the men are 50 years old or older; about 40% of the women are less than 50 years. Only about 10% of our patients have been less than 30 years old; susceptible persons of this age include (1) women in the postpartum state or undergoing septic abortion, (2) children with severe burns, malignant neoplasms, or hematologic diseases, and (3) premature infants.

Portal of Entry

In about 50% of our cases there was a urinary portal of entry. The biliary tract was the portal in 10%, and the rest of the gastrointestinal tract in 15%. The female genital tract was indicted in 5%. In another 5%, other sources such as skin, postopera-

Continued

*Read at the meeting of the American Academy of General Practice, Lake Okoboji, Iowa, June 18, 1966.

tive wounds, and the respiratory tract were responsible. In 15% of our cases a portal was not evident. In 50% this type of bacteremia has occurred after surgical or manipulative procedures; two thirds of the procedures were genitourinary and one third, gastrointestinal.

The respiratory tract, although not a common portal for gram-negative bacteremia in general, may give entry to *Bacteroides* infection. *Pseudomonas* bacteremia also has had a respiratory portal, as in patients inhaling contaminated aerosols; but such portals as the skin in victims of burns and the urinary tract are more common in *Pseudomonas* infection. These portals for *Pseudomonas* bacteremia share the possibility of exposure to contaminated instruments and medications.

In the 15% of our cases in which a portal was undetected, there was a high incidence of hematologic disease. Hematologic disease, contradistinct to other predisposing conditions, is usually characterized by a clinically inapparent portal for supervening bacteremia. Recent studies in fatal cases of bacteremia due to gram-negative bacilli disclosed that nidi of infection in the lung and mucous membranes of the upper respiratory passages and alimentary tract were the sources of bacteremia in most patients with hematologic disease.⁷

Predisposing Nidi of Infection

Among nidi of infection from which bacteremia may originate, in our experience pyelonephritis, cholangitis, and conditions associated with varying degrees of peritonitis, such as appendicitis and diverticulitis coli, are most common. Cutaneous, respiratory, and other nidi of infection are less common. These nidi are often disturbed by surgical or manipulative procedures or are associated with other predisposing disease or treatment that alters host mechanisms involved in localizing infection.

Predisposing Noninfectious Diseases

Advanced arteriosclerosis, which occurred in about 20% of our patients, may be indirectly predisposing because victims of

strokes, and those undergoing surgery for abdominal aneurysms and the like, frequently require urinary catheters. Infected peripheral gangrene is an additional and more direct portal.

Malignant neoplasms were present in about 10% of our patients; in three fourths of these, bacteremia occurred after urologic procedures or gastrointestinal operations. Bacteremia also followed certain medical regimens, especially the use of radiomimetic drugs.

Hematologic disorders were present in about 15% of our patients. Diminished resistance to infection in these diseases may reflect (1) defects in gamma-globulin, as in chronic lymphatic leukemia, lymphoma, and multiple myeloma; (2) inadequate neutrophilic response, as in acute leukemia, chronic granulocytic leukemia, agranulocytosis, or aplasia; and (3) iatrogenic factors including therapy with adrenal steroids, antimetabolites, and antibiotics. In hematologic diseases, bacteremia is not uncommonly due to *Pseudomonas* organisms, to bacteria infrequently causative otherwise of overwhelming infection such as *Alcaligenes* organisms; and the incidence of polymicrobial infection is higher also.⁸

Of our patients, about 10% had diabetes mellitus in which the portal is almost always urinary.⁹ Diabetic complications like coma, cesarean section, and amputation frequently require urinary catheterization, further enhancing bacteremia.

Five per cent of our patients had severe hepatic disease in which bacteremia may reflect "reseeding" of the blood with bacilli phagocytized, but not killed, in Kupfer's cells. In such patients the number and phagocytic activity of Kupfer's cells are normal, but the cells appear unable to destroy ensnared organisms. In our experience, infectious nidi in the biliary passages, urinary tract, or peritoneum, especially if disturbed by surgery or manipulation, appear to be the sources of bacteremia in most of these patients.¹⁰

Predisposing Therapies

Predisposing therapies include surgery and instrumentation, as occurred in about

half our cases. Two thirds of these procedures were genitourinary and one third were gastrointestinal. The most common procedure was transurethral prostatic resection, with cystoscopy a close second. Among gastrointestinal procedures, the three most common operative sites were the biliary tract, the intestines, and the stomach. Bacteremia, especially that due to *Pseudomonas* organisms, may occur on contamination of a heart-lung machine or hemodialysis apparatus; fortunately, in our group practice, bacteremia has not occurred after infusion or transfusion.

In about 20% of our patients, the penicillins and allied drugs administered prior to the onset of bacteremia appeared to have depressed gram-positive elements of the normal microflora, allowing overgrowth and bloodstream invasion by gram-negative elements.

In 15% of our cases adrenal glucocorticoids had been employed before the onset of bacteremia, most often to control hematologic diseases. McCabe and Jackson² noted that prior administration of steroids increased the frequency of bacteremic shock and the fatality rate among their patients.

Five per cent of our patients were receiving antimetabolites when bacteremia occurred; these patients had hematologic or malignant disease.

Less than 5% of our patients were receiving irradiation when bacteremia occurred; these patients also had hematologic or malignant disease.

Other potentially predisposing therapies include the subcutaneous or intramuscular injection of contaminated medications, the inhalation of contaminated aerosols, and "cut-down" sites and areas of thermal trauma which become infected.

Clinical Features

About 98% of our patients had fever that ranged from 101 to 106 F (oral); such fever may be intermittent, remittent, continuous, or variable. The onset of bacteremia is manifested by fever and chills in about 60% of patients, by spiking fever without chills in approximately 25%, and by a gradual onset of malaise and fever in about

15%. Twenty to 30% manifest their infection by sudden circulatory collapse, or bacteremic shock.

Headache is common. All patients have some degree of prostration, but delirium and stupor are rare. Vague myalgia, restlessness, apprehension, and agitation are initial manifestations in a few patients. Coma is rare and usually reflects an underlying condition, such as hepatic failure, uremia, or diabetic acidosis. Anorexia is usual, but vomiting, abdominal distention, and diarrhea often reflect an underlying disease such as chronic ulcerative colitis, uremic enterocolitis, or pelvic abscess. Diarrhea can be manifest in bacteremia in the absence of underlying intestinal disease, and classically this suggests *Bacteroides*¹¹ or *Salmonella* infection, although it may also be associated with infection due to other gram-negative bacilli. Diarrhea occurring after bacteremia is established should suggest staphylococcal enterocolitis complicating antibiotic therapy. Hyperventilation in our experience is more characteristic of advanced shock and has not been a common presenting sign of that complication.

Leukocytosis is usually present, but a normal number of leukocytes is not rare. In an occasional case, leukopenia shortly replaced by leukocytosis is the initial manifestation of complicating shock. In some cases of established *Pseudomonas* bacteremia, marked and persistent leukopenia occurs. Mild anemia is common. Of course, these generalizations may be considerably modified by findings in patients having underlying hematologic diseases.

Albuminuria, hematuria, and pyuria usually reflect underlying disease. Azotemia, hyperkalemia, and decreased values for serum sodium, chloride, and carbon dioxide-combining power occur especially in patients having an hypotensive episode. Recently, the concentrations of lactate and pyruvate in the blood have been studied as possible indices of impending shock and its reversibility. Metabolic acidosis, which is common in bacteremic shock, may be due largely to an increase in lactate radicals.¹² As a pre-

Continued

liminary impression, the severity of shock appears to parallel the concentration of blood lactate; a high level of blood lactate, or lacticacidosis as it has been called, early in shock appears to indicate a poor prognosis. An initial value of less than 10 mEq per liter which drops rapidly with treatment may indicate a better prognosis. Significant lacticacidosis occurs when the ratio of lactate to pyruvate is greater than 10 to 1. The correlation appears to be good between rising levels of blood lactate and decreasing values for serum bicarbonate and arterial pH. The genesis of lacticacidosis appears to reflect tissue hypoxia resulting from reduced blood flow which increases anaerobic metabolism with a consequent rise in lactate levels. An elevated value for serum phosphate in the presence of acidosis may indicate lacticacidosis. A corroborative test of significant lacticacidosis is the determination of the anion gap $[(Na + K) - (HCO_3 + Cl)] = 17$ mEq/L wherein a gap greater than 17 is taken as being representative of true acidosis. Removal of lactic acid from the blood appears to be a function of the liver and consequently lacticacidemia may occur when the blood supply of the liver is impaired or the liver is damaged by disease. In such patients as those having impaired renal function or diabetes mellitus, one should not fail to consider the multiple factors possible in the genesis of the acidosis.

Notable clinical features sometimes suggest that the pathogen is *Pseudomonas*. First are skin lesions, most often seen in the anogenital regions and axillae and known as "ecythma gangrenosum." The lesions begin as macules or vesicles, become pustular, and may slough to form necrotic ulcers. Biopsy of the lesions may reveal bacilli in the walls of blood vessels, and culture may reveal the *Pseudomonas* organisms. Another possible feature of *Pseudomonas* bacteremia is severe leukopenia, at times associated with thrombocytopenia. One notes that patients with underlying hematologic disease are predisposed to *Pseudomonas* bacteremia. Conversely, in those without such underlying disease in whom *Pseudomonas* bacteremia develops, secondary

hematologic findings may be a manifestation of the infection. Petechiae and rarely bluish green discoloration of the nail beds also may characterize *Pseudomonas* bacteremia. Jaundice may be noted in bacteremia due to other gram-negative bacilli but is of increased incidence in *Pseudomonas* bacteremia.

Diarrhea beginning prior to antibiotic therapy and ceasing with recovery occurs in about one third of cases of *Bacteroides* bacteremia. Diarrhea suggests *Bacteroides* or *Salmonella* infection but also is noted in bacteremia due to other gram-negative bacilli. In about one third of cases of *Bacteroides* bacteremia, foul-smelling exudates are noted, but only rarely do these have the stale, butterlike, or cheesy odor said to be characteristic of *Bacteroides* infection. Delayed response in *Bacteroides* bacteremia suggests the likelihood of a suppurative locus, requiring surgical drainage. However, control of *Bacteroides* bacteremia, even in the absence of localized suppuration, may require more time than does bacteremia due to other gram-negative bacilli. Localized suppuration occurs in bacteremia due to other gram-negative bacilli but appears to be of higher incidence in *Bacteroides* bacteremia. Unlike the findings of other investigators, clinical evidence of thrombophlebitis has not been common in our patients with *Bacteroides* bacteremia.¹¹

When bacteremia complicates septic abortion, one considers coccal and clostridial infection, but gram-negative bacilli commonly are responsible; smears of the cervix may aid in this distinction prior to reports of blood cultures.

Complications

Bacteremic shock due to gram-negative bacilli is said to be present when the following criteria are fulfilled: (1) a sustained, often precipitous, drop in systolic blood pressure to 80 mm. of mercury or below is noted in an individual previously normotensive; (2) gram-negative bacilli are recovered from blood cultures obtained during or shortly preceding the hypotension; and (3) the clinical picture is compatible with bacteremia, with other causes of shock excluded.

The blood pressure may not faithfully reflect the status of the microcirculation to various organs; consequently, inadequate tissue perfusion may be present prior to development of hypotension. Nevertheless, sustained systemic arterial hypotension remains an essential clinical manifestation of bacteremic shock since more sensitive methods of detection are presently unavailable.

The precise pathogenesis of human bacteremic shock is at best incompletely understood. Normal blood pressure reflects a satisfactory relation of vascular capacity to blood volume; significant change in either of these variables is reflected by a change in the blood pressure. When vascular capacity is increased by dilatation of the vessels, blood is sequestered therein and diminished amounts are returned to the heart. Incomplete cardiac filling results in reduced cardiac output, hypotension, and diminished arterial blood flow. Consequently, there is inadequate perfusion of vital tissues and organs with oxygenated blood. Although definite proof is lacking, liberation of the endotoxin of gram-negative bacilli into the systemic circulation likely initiates the complex pathophysiologic response present in bacteremic shock. Microcirculatory experiments indicate that endotoxin acts indirectly on blood vessels, apparently through the medium of a heat-labile component in blood, and induces tetany-like activity of the vascular bed near the arteriolar level. Initially vasoconstriction predominates, but eventually there is vascular atony with consequent stagnation of blood in the peripheral capillary beds. The resulting decreased cardiac filling may eventuate in diminished arterial blood flow as previously noted, the consequence being that anoxia prevents normal cellular metabolism and that anaerobic cellular reactions dominate, with formation of acid metabolites to the point of metabolic acidosis. It should be stressed that in bacteremic shock, blood volume usually is adequate but perfusion is ineffective because of peripheral pooling. As data accumulate, it becomes apparent that human bacteremic shock is not the result of a single hemodynamic aberration;

some patients have reduced cardiac output and normal or increased peripheral arterial resistance, whereas others may have essentially normal cardiac output and reduced peripheral arterial resistance.

In these cases, shock may be obscured by warm skin, bounding pulse, and fever, and only hypotension may indicate the presence of shock clinically. The synoptic symptomatology of bacteremic shock consists of increasing temperature and pulse rate, with decreasing blood pressure and urinary output. As a generalization, in patients having advanced bacteremic shock, frequently there is a reduction in urine flow to 20 ml. or less per hour. The complication has two symptomatic and prognostic stages. In stage I, which is characterized by "infectious" symptomatology, the patient is alert and has warm flushed skin, full bounding pulse, progressive pyrexia, moderate hypotension, and moderate urinary output. If the complication is recognized in stage I and appropriate treatment instituted, the prognosis is good. In stage II, which is characterized by "shock" symptomatology, the patient is semicomatose and has pallid, cold damp skin, collapsed superficial veins, feeble pulse, shallow hyperpnea, marked hypotension, and progressive oliguria, and the prognosis is poor.

In addition to bacteremic shock, there are two other significant complications of bacteremia due to gram-negative bacilli and its management, namely metastatic suppuration and superinfection. *Bacteroides* organisms, although not the sole bacterial cause of metastatic infections, have an increased propensity to cause such lesions. Metastatic infections may include abscesses of the liver, lung, and kidney.

In 5 to 10% of cases, superinfections occur; these include enterocolitis, bacteremia, pneumonia, pyelonephritis, and parotitis. Staphylococci usually are responsible, but sometimes other organisms, such as *Streptococcus faecalis* are causative. Approximately one fourth of superinfections are fatal; but malignancy, leukemia, and the like usually cause the death.

Continued

Antibacterial Therapy

In-vitro inhibition tests are mainly of retrospective value in the management of bacteremia, because therapy often is begun empirically before such data are available. To postpone therapy until the results of such tests are reported would mean a delay of 24 to 48 hours and an increased chance of mortality. Awareness of a primary nidus of infection, underlying disease, or predisposing therapy may suggest causation by gram-negative bacilli and initiation of a pertinent regimen until microbiologic data are forthcoming.

My colleagues and I initiate empiric antibiotic therapy, either on report of positive blood cultures or in cases wherein bacteremia is likely, when blood has been drawn for culture. In our cases, a tetracycline and streptomycin, or alternatively, chloramphenicol and kanamycin, have been the regimens given most often under these circumstances.

If on subsequent receipt of inhibition tests the bacilli resist the drugs being given and if the patient is not progressing well, the empiric regimen is changed. In cases wherein progress has been unsatisfactory after 12 to 24 hours and inhibition tests remain unreported, the regimen may be changed empirically. In the latter cases, in addition to the two regimens mentioned, one considers use of polymyxin B or colistin in replacement of streptomycin or kanamycin. More recently we have been investigating the combined use of cephalothin and colistin (or polymyxin B) given under these circumstances. Other possible empiric regimens that may warrant investigation are cephalothin plus kanamycin and ampicillin given with kanamycin, colistin and polymyxin B.

In actual management of these patients, on report of positive blood cultures or after blood is drawn for culture in those having clinical bacteremia, 500 mg. of a tetracycline or chloramphenicol is given by mouth every six hours. If shock jeopardizes intestinal absorption, a tetracycline is given intravenously in amounts of 500 mg. every eight to 12 hours. Alternatively, chloramphenicol can be given intravenously in similar amounts every six to eight hours. As much

as 1 gm. of streptomycin — or 0.5 gm. of kanamycin if associated staphylococcal infection or refractoriness appears to indicate — is given intramuscularly every 12 hours. When polymyxin B or colistin is used, 50 mg. is given intramuscularly every 6 to 8 hours. Cephalothin is given in amounts of 0.5 gm. every four to six hours intramuscularly, or 1 gm. may be given at the same time intervals, or more often by the intravenous route.

If renal function is impaired, the dose of the tetracycline, streptomycin, kanamycin, polymyxin B, or colistin is correspondingly reduced.

There are disadvantages of empiric use of combined antibiotic therapy. These include the dual depressive effect on the gram-negative elements of the flora, making superinfection more likely. However, periodic study of the sputum and stools during therapy may reveal any floral changes and impending superinfection. Streptomycin, kanamycin, polymyxin B, colistin, and possibly cephalothin are nephrotoxic; excepting cephalothin, these drugs may cause a curariform effect that is manifested by respiratory depression. Chloramphenicol is hematotoxic. Streptomycin and kanamycin are ototoxic, but the latter is more likely to cause deafness. Polymyxin B and colistin also may cause cerebellar ataxia and other neurologic complications. In view of current results on in-vitro tests of bacterial susceptibility, which will be discussed in greater detail later, streptomycin-tetracycline may not provide antibacterial "coverage" to the degree obtainable with alternative regimens. Moreover, combined therapy entails the introduction, or an increased number, of parenteral injections and is more expensive.

It may be pertinent to recall that the incidence of ototoxicity after use of streptomycin is minimized if one avoids a dose in excess of the patient's renal tolerance and administers it for a minimal period. Fear of ototoxicity should not completely interdict use of streptomycin, but one should not give it indiscriminately. Perhaps one should exercise greater caution in the use of kanamycin, since it is more likely to cause deafness and,

like dihydrostreptomycin, has caused deafness of delayed onset. Streptomycin is more likely to cause vestibular damage, which can be compensated considerably by visual mechanisms.

With the advent of newer drugs, we have reevaluated our policy of the empiric use of combined antibiotic therapy. Use of colistin as a single agent, like polymyxin B, has a disadvantage because *Proteus* and *Bacteroides* organisms usually are resistant to it. Kanamycin is inadequate, as a single agent, because a number of *Pseudomonas* and most *Bacteroides* are insensitive. Ampicillin is inactive against most *Klebsiella-Aerobacter* organisms, most *Proteus* bacilli that are indole-positive, and *Pseudomonas* organisms. Cephalothin is not active against all *Klebsiella-Aerobacter* organisms, *Bacteroides*, and indole-positive *Proteus* bacilli and usually is inactive against *Pseudomonas*. To date, there is no single agent available that assures complete "coverage" against gram-negative bacillary infections. As aforementioned, we are currently investigating cephalothin and colistin (or polymyxin B) given in combination in the empiric management of bacteremia due to gram-negative bacilli. Possible a priori objections to this combination are that all indole-producing *Proteus* organisms and *Bacteroides* may not be susceptible to its effect; however, thus far the regimen has been very satisfactory.

Exemptions from the empiric rule of combined antibiotic therapy depend on various features in the individual case, examples of which include (1) identification of the pathogen, that is, identification of *Pseudomonas* would indicate use of polymyxin B or colistin, (2) refractoriness to the empiric regimen, or (3) the reporting of tests of in-vitro bacterial susceptibility indicating a single agent to be effective.

Currently, when the patient's course is unsatisfactory and microbiologic data are reported, the empiric regimen may be replaced with a more pertinent drug, in keeping with results of tests of in-vitro bacterial susceptibility. Against *E. coli*, such drugs as ampicillin, cephalothin, polymyxin B, or colistin

may be applicable. However, some workers avoid the use of polymyxin B and colistin when possible in nonpseudomonal infections because the drugs may produce relatively low serum and tissue levels. As a generalization, strains of *E. coli* are susceptible to streptomycin and the tetracyclines and cephalothin in about 50% of cases; these bacilli are susceptible to kanamycin, chloramphenicol, and ampicillin in 80% or more of cases. The same generalization is applicable to *Klebsiella-Aerobacter* organisms except that only about 10% of these bacilli are susceptible to ampicillin.

Among other drugs, penicillin G, ampicillin, cephalothin, and novobiocin are active against the indole-negative *Proteus mirabilis*, which causes 80 to 90% of clinical infections due to *Proteus* organisms. Cephalothin is active in 10 to 20% of infections caused by indole-positive *Proteus* organisms, that is, *P. vulgaris*, *P. morganii*, and *P. rettgeri*; chloramphenicol also may be effective, but differences between in-vitro and in-vivo results are frequent with the drug against these organisms. Consequently, kanamycin may be the drug of choice against indole-positive organisms. Polymyxin B or colistin is used especially against *Pseudomonas* organisms. Despite the availability of the newer agents, a tetracycline often is preferred in bacteremia due to *Bacteroides* organisms; penicillin G may be active against certain strains of *Bacteroides*. Ampicillin, cephalothin, and kanamycin, in addition to the tetracyclines and chloramphenicol, may be applicable to *Salmonella* infections. It is to be noted that cephalothin may not eradicate infections due to certain gram-negative bacilli, including *Salmonella*, despite in-vitro indications of susceptibility.

The use of intravenously administered penicillin G in doses of 20,000,000 to 60,000,000 units daily has been suggested in infections due to *Enterobacteriaceae*, excepting *Proteus* organisms. *P. mirabilis* is sensitive to smaller dosage, whereas other *Proteus* organisms are resistant to even heroic doses. Because other effective drugs have become available, currently there is infrequent need

Continued

of penicillin G therapy for infections due to *Enterobacteriaceae*, except for some of those due to *P. mirabilis*.

It may be pertinent to mention here that strains of bacteria may resist antimicrobial drugs because these organisms carry so-called R (resistance) factors. The R factor appears to represent genetic material (DNA) not attached to the bacterial chromosome but floating free in the bacterial cytoplasm. This extrachromosomal material appears to be transferable among organisms by bacterial conjugation; antibiotic-resistant bacteria can transmit the property of resistance to susceptible bacteria when grown together. Transfer of resistance has been noted among the *Enterobacteriaceae* as well as among *Pseudomonas* organisms and staphylococci. The incidence of bacterial strains carrying R factors appears to have increased in direct proportion to the use of antibacterial agents.

Clinical circumstances were such that a single agent has been employable in little more than one third of our cases. There is no argument against the premise that best results are obtained when the bacilli are susceptible in vitro to the drug employed, but the difficulty lies in the unavailability of such data when the clinical status of the patient requires initiation of therapy.

Since polymicrobial infections are of increased incidence in *Bacteroides* bacteremia and in patients with hematologic diseases, several drugs may be given simultaneously: for example, tetracycline for *Bacteroides* and penicillin G and streptomycin for an enterococcus. However, one tries to minimize the number of drugs because their indiscriminate uses may increase bacterial resistance, since such resistance appears to manifest the amount of a drug used in a given area. Ampicillin and cephalothin may prove useful in selected polymicrobial infections.

Grand Rounds

*Pseudomembranous Enterocolitis**

HENRY T. SMITH, M.D.
Medical Resident

PSEUDOMEMBRANOUS ENTEROCOLITIS is a disease of obscure etiology. Although awareness of the entity goes back to the 1800s, much remains unanswered as to etiology, pathogenesis, and therapy. Controversy persists regarding the relationship to staphylococcal enterocolitis. Synonyms that are commonly found in the literature include diphtheritic colitis or enterocolitis, acute necrotizing hemorrhagic enterocolitis, staphylococcal enterocolitis, and ischemic colitis.

History

Birnbaum¹ refers to a description of this entity by Billroth in 1867 in which the possibility of sepsis producing the lesion was mentioned. However, Finney is credited with the first published account of this process.² In 1893 he described a case of bloody diarrhea that occurred 10 days after gastric surgery in a 22-year-old negro female. The patient died eight days later and at autopsy showed "diphtheritic" enteritis of the terminal ileum and colon. No enteric pathogens were found and the microscopic sections were not described. However, Bennett et al. reviewed the sections in 1956 and noted numerous gram-positive cocci in the intestinal wall.²

Scattered reports³ early in the 20th century include Riedel's description in 1902 of five postoperative patients who developed a clinical picture of diarrhea and circulatory collapse and died within four or five days from the onset of symptoms. At autopsy "diphtheritic" lesions of the intestine were found. In 1910 Wertheim described "diphtheritic" enteritis in three patients in a series of 500 cases of radical pelvic exenteresis for carcinoma of the cervix.

The first large series analyzed in this country was that of Penner and Bernheim⁴ in 1939, consisting of a review of 40 cases over a 10-year

*Medical Grand Rounds, Hennepin County General Hospital, June 21, 1966.

Continued

period. They discussed the occurrence of the lesion subsequent to such operative procedures as craniotomy, radical mastectomy, and lobectomy, as well as abdominal surgery. They also discussed its occurrence in such nonsurgical disorders as extensive burns, gastrointestinal hemorrhage, and fractures of the spinal column without operation. It was suggested that shock was the common denominator associated with the disease, and it was proposed that this was of etiologic significance.

Dixon and Weisman⁵ reviewed records at the Mayo Clinic for a 10-year period and added 23 cases to published accounts of the occurrence of the entity in postoperative patients. In their series circulatory collapse was associated with the clinical onset of intestinal complications. It was observed that the interval between shock and death was so brief in many cases that it was unlikely that the pseudomembranous lesions could have developed as a result of the shock. Therefore they could not confirm the shock theory of Penner.

At this point one might conclude that prior to 1950 this disease was recognized only on the surgical wards; it is also true that most of the previously mentioned cases were preceded by abdominal surgery. However, in 1952, Kleckner et al.⁶ reviewed the clinical and pathological findings in 14 patients who had not had abdominal surgery. The process was considered the immediate cause of death in seven of the 14 cases. The autopsy findings were the same as those noted in the postoperative cases. All of the patients reported manifested circulatory collapse, but it could not be determined whether this preceded or followed the onset of the intestinal lesion. No increase was noted in the incidence of the disease since antibiotics had been used for the treatment of intestinal lesions. It was, therefore, concluded that the use of such drugs could not be implicated in the pathogenesis of the entity.

Pettet et al.⁷ described 94 patients who died in the postoperative period with extensive pseudomembranous involvement of the gastrointestinal tract at the Mayo Clinic during the period 1925-1953. It was interesting to note that prior to 1948 there were no instances of correct ante-mortem diagnoses in this group; subsequent to that time the disease was correctly diagnosed in 14 of 26 cases. These workers could demonstrate no significant increase in the incidence of the disease since the advent of antibiotics. There were 45 cases found before, as opposed to 49 cases noted after antibiotics became available. Forty-four percent of the patients in the study had carcinoma of the colon. Although the investigators were unable to find any one etiologic factor, it was thought that the incidence of colon carcinoma was of significance. Importance was also attached to the observation that 71 of the 94 patients had some type of infectious process, usually pneumonia or peritonitis. Some of the patients seen during the latter part of the study had large numbers of staphylococci in culture of feces at necropsy. These organisms were quite resistant to the usual antibacterial drugs. It was, therefore, suggested that a change in the normal balance of the intestinal flora may have been important. In this series shock was noted after the onset of the abdominal symptoms and was, therefore, considered secondary to, rather than productive of, the intestinal lesion.

Clinical Course

The triad of symptoms which may be helpful in recognizing the onset

of this process consists of: (1) Elevated temperature, (2) abdominal distention and/or diarrhea, and (3) shock.⁸ The most significant clinical features are the sudden onset of profound circulatory collapse which is resistant to the usual supportive measures, and the presence of watery diarrhea.⁶

An often-seen pattern consists of a relapse noted after an initial period of improvement in a patient being treated with antibiotics for various diseases.⁹ There may be a sudden rise in temperature after an afebrile period. The rapid onset of lethargy, mental aberrations, nausea, vomiting, abdominal distention, diarrhea and collapse are characteristic.^{2,9} In the surgical patient the average time of onset is three days post-operatively, although Pearce¹⁰ noted a range of two to 12 days. The diarrhea is not invariable but usually consists of the explosive onset of watery-green or yellow-brown stools. The absence of diarrhea is attributable to adynamic ileus as well as to the sudden onset of the disease which may result in severe outpouring of fluid material into the intestinal lumen with marked dehydration, collapse and death before the diarrhea can occur.

Pain is not a prominent feature, but in those who develop this symptom it ranges from mild discomfort to severe cramps.¹¹

Pathology

The site of involvement of this disease may be anywhere in the G.I. tract but the lesions are found most frequently in the small and large intestine. Of the 94 patients studied by Pettet, 44 had small intestine involvement, 24 small and large intestine involvement, and 12 large intestine lesions.

The Pseudomembrane

At autopsy the intestinal tract is usually greatly dilated and filled with liquid feces. The mucosal surface is generally lined with a friable yellow-green or tan, sticky pseudomembrane that occurs either in isolated plaques or as an extensive process involving several feet of intestine. It is usually readily separated from the underlying mucosa which may be normal or diffusely injected.

Microscopically the membrane consists of a mixture of necrotic cellular debris, fibrin and a variable number of inflammatory cells and mucus, which forms as a result of fibrinoid necrosis of the superficial mucosa. Simultaneously the subjacent glandular structures secrete an excessive amount of mucus. The exudate and the necrotic superficial zones of mucosa coalesce to form the membrane. As the disorder progresses the entire mucosa undergoes coagulative necrosis, and at this stage the membrane may slough, leaving an ulcer with a pyogenic surface which may subsequently penetrate the muscle coat. The submucosa is congested and edematous and may have deposits of fibrin in it, but rarely is there much leucocyte infiltrate, although phagocytes may be quite numerous. In Dearing's^{12,25} study involving a comparison of those cases in which *S. aureus* was cultured at autopsy with those cases in which the organism could not be cultured, there were no demonstrable gross or histologic differences in the intestinal lesions.

Continued

Histologic Sequence

McKay and his group¹³ were able to produce pseudomembranous enterocolitis experimentally in dogs by the administration of incompatible blood into the aorta with concomitant surgical trauma. They traced the histological sequence of events and noted: (a) the earliest changes consisted of thrombosis of the capillaries which initially was not accompanied by necrosis; (b) shortly thereafter the mucosal tissue infarcted with hemorrhage into the connective tissue of the villi and into the lumen; (c) subsequently the mucosal surface was covered with a layer of necrotic tissue from the infarcted superficial mucosa, fibrin, mucus, red blood cells and leukocytes.

In the experimental situation the thrombi appear practically instantly. The development of necrosis is a very rapid process and was observed in one animal two and one-half hours after the incompatible transfusion was started.

Etiologic Factors

In a discussion of the etiology of this disease in 1956, Prohaska et al.¹⁴ suggested that it was incorrect to associate pseudomembranous enterocolitis exclusively with abdominal operations or the use of intestinal antibiotics. Reference was made to the available literature regarding the occurrence of the disease after operations on the brain and breast as well as its occurrence without associated use of antibiotics.

*Staphylococcus Aureus*¹⁴

(1) Pseudomembranous enterocolitis is an infectious disease produced by *S. aureus*. This contention was felt to be supported by the large number of cases in the world literature in which staphylococci were isolated in pure culture. (2) *S. aureus* does not establish itself in the intestinal tract containing the usual bacterial flora, as evidenced by the work of Dack who, in his studies on food poisoning, was seldom able to recover staph in the stools of volunteers who took the microbe by mouth. (3) Shock and the fatal course of the disease are enhanced by micrococcal enterotoxin. This was supported by experiences with the enterotoxin in the majority of strains of staph associated with fatal pseudomembranous enterocolitis. (4) The effect of the enterotoxin may be negated by the administration of ACTH. In this regard the group reported their experiences in two patients who had the diagnosis confirmed at laparotomy and then had dramatic response to ACTH. It is interesting that in an earlier publication discussing this mode of therapy Prohaska stressed the importance of differentiating staph enteritis from pseudomembranous enterocolitis since the former might respond adversely to the drug. "Any bacterial disease would have been markedly aggravated by corticotropin . . . we believe therefore, that the disease is not an infection."¹⁵

The frequent recovery of staphylococci from the diarrheal stools of patients with this clinical diagnosis has led others to conclude that the organism is causally related to the disease. Bockus² indicates that greater than 50 percent of authenticated cases of pseudomembranous enterocolitis have been attributed to staphylococcal infections in association with antibiotic therapy. It has been suggested that the organism was not cultured prior to 1950 because the media used were selective for intestinal pathogens and were not suitable for growth of staphylococci.⁷

Antibiotics

There is adequate documentation in the literature that this entity was recognized as a postoperative complication long before the advent of antibiotics.¹ However, reports vary as to the change, or lack of change, in incidence of the disease with the recent increased use of broad-spectrum antibiotics.

The exact relationship between broad-spectrum antibiotics and pseudomembranous enterocolitis is not clear. It is well known that such antibiotics can produce a change in the intestinal flora with suppression of normal bacteria and associated increased growth of resistant organisms such as staphylococci in the colon. However, the mechanism of production of the distinct lesion is obscure, particularly in the small intestine which is usually almost entirely free of bacteria.¹⁷

The possibility of an infective etiology is in part suggested by the experimental production of pseudomembranous enterocolitis in chinchillas by the oral administration of staphylococci or enterotoxin or both in association with antibiotic therapy.¹

Dearing¹² showed that fatal pseudomembranous enterocolitis may occur both with and without culturable *Staphylococcus aureus* in the intestinal tract and that severe staphylococcus enteritis may exist without pseudomembranes in the intestine. He emphasized that although fatal pseudomembranous enterocolitis may occur in patients who have not received antibiotics prior to or during the course of their enteritis, patients with staphylococcus enteritis almost always have received antibiotics which affect the intestinal flora in such a way that the growth of staphylococcus is encouraged.

Several years ago Palmer¹⁹ suggested that too much blame had been placed on antibiotics in the etiology of this disease. He thought that although the proliferation of virulent staphylococci might add to the surface damage, the basic cause of the process was probably related to factors which depressed the intrinsic mucosal vitality. He presumed a hypoxic process to be the most likely etiology and suggested a local vascular fault as being responsible for the sudden infarction of many feet of mucosa with sparing of the deeper tissue.

Shock

Birnbaum¹ reviewed 40 cases diagnosed at autopsy and found that in all cases there was a concurrent problem with either shock, anemia, heart failure, hydrothorax or an inflammatory pulmonary condition. He pointed out that all of these factors are likely to lead to hypoxia, which may well have been the common factor involved.

Markley et al.²⁰ reviewed 14 cases with a diagnosis of pseudomembranous enterocolitis made at post-mortem examination. These cases demonstrated in varying frequency many of the associated factors that are often ascribed etiological significance, including shock, surgery, previous antibiotic therapy, staphylococcal infections, intestinal obstruction. The reviewers concluded that none of these factors occurred with sufficient preponderance to suggest a constant causal relationship. It was suggested that the common denominator in these cases consisted

Continued

of an impairment of the blood supply of the intestine. The workers attached significance to the finding that in those cases with localized ischemia, the areas with most severe pseudomembranous involvement were those adjacent to the ischemic bowel, although other portions were also involved. It was concluded that "the evidence at hand indicates that pseudomembranous enterocolitis is a pathologic entity resulting from the action of a variety of noxious factors in the presence of an underlying disorder characterized by a deficiency in the volume of blood or in the nutrient quality of the blood reaching intestinal tissue."

Although this is a logical conclusion on the basis of their series, it is unlikely that this represents an essential condition in all cases, since this entity has been demonstrated in children without vascular abnormality or mechanical embarrassment of intestinal blood flow.

Intravascular Coagulation

In the experimental production of the disease in dogs, McKay and his coworkers concluded that the trigger mechanism involved was an episode of intravascular coagulation and that the pseudomembrane was caused by thrombi in the mucosal capillaries. The localization of the thrombi in the intestine was explained by "compensated shock" which was due to the surgical trauma and the concomitant pooling of blood in the splanchnic capillary bed. The pathology of the lesions was considered identical to that found in man; however, the authors readily admitted that there was uncertainty as to the extent of applicability of these experiments in the clinical syndrome.

In a follow-up report these investigators²¹ indicated that the experimental production of these lesions could be prevented with preheparinization of the animals. They suggested that the syndrome resulted from two distinct phenomena: (1) "circulatory collapse," assumed to be produced by intravascular coagulation in submucosal shock and usually occurring postoperatively. Antibiotics may or may not have been used. Diarrhea is not necessarily present. Mortality is high in this group. (2) A "diarrhea type" resulting from alteration of the intestinal bacterial flora with the predominant growth of staphylococci and the development of staphylococcal enteritis. This type may or may not have been preceded by surgery and is most often associated with antibiotic therapy. Shock is said to develop more gradually in these cases, and the mortality is low in adequately treated patients.

The authors concluded by proposing that a combination of bacterial enteritis and capillary thrombi may actually be the most common etiology of this phenomenon.

Obstructive Mechanism

Hale and Cosgriff¹¹ have discussed a variety of possible etiological mechanisms, including a suggestion by Pettet that obstruction of the G.I. tract may be of significance in that the resulting alteration of permeability of the bowel wall could predispose to invasion by pathogenic microbes. Another possible mechanism suggested is that pseudomembranous enterocolitis may represent a local tissue reaction similar to the Shwartzman phenomenon.* Sensitivity of the patient to the

*See Test Your Word Score Page 363.

antibiotic is another consideration. It is thought that this would best explain cases in which the syndrome develops a few hours after administration of the drug.

A review of the possible etiologies was perhaps best summed up by Baggenstoss⁷ in 1954 when he stated ". . . there are probably many causes of this lesion. The manner in which the intestinal mucosa can react to injury is limited; formation of a pseudomembrane probably can be brought about by a wide variety of toxic and infectious agents. Consequently one set of factors may have been operative in the pre-antibiotic period and now a different set of factors may be responsible."

The confusion regarding the etiology of the lesion stems from the variety of circumstances under which it is noted.¹⁴ It may be found with and without surgery, with and without antibiotics, and with and without staphylococci. It is difficult to conceive of the disease as a distinct entity until the opposing factors are made to fit into some pattern that encompasses all variations.

Diagnosis

Sudden Diarrhea

This diagnosis should be considered in any patient receiving antibiotic therapy who develops diarrhea and fever. Sudden dehydration in these patients should suggest loss of fluid into the bowel, if there is no diarrhea. There is no other pathologic entity, with the exception of cholera, that produces such profound shock and dehydration as pseudomembranous enterocolitis.

Increase of Gram-Positive Cocci

A smear of stool showing a relative increase in gram-positive cocci helps to confirm the diagnosis in those cases in which staphylococci are associated. Hale and Cosgriff have indicated that sigmoidoscopy may reveal the typical membranous involvement; a smear taken from the lesion may reveal organisms that were not detected on the routine smears. The diagnosis is particularly difficult in the postoperative patient, since surgical complications may be responsible for the gastrointestinal symptoms. There are no pathognomonic clinical or radiologic findings.

Radiologic Findings

In the series studied by Feinberg²² the radiologic findings were primarily limited to the small intestine and generally suggested incomplete or complete obstruction. Persistence of the distended intestinal loop or loops for days, or until death, constituted the most striking finding and emphasized the challenge of excluding obstruction by roentgenologic means. Awareness of the possibility of the lesion and a high index of suspicion are of the utmost importance, since early therapy may be life-saving. In Pearce's study¹⁰ it was noted that in three patients who recovered there was an average interval of 5.7 hours from the initial manifestations to therapy; whereas in those cases ending fatally and recognized clinically there was an average of 40 hours before the disease was suspected and treatment begun.

Continued

Treatment

Because of the frequent isolation of staphylococci in cases of pseudomembranous enterocolitis, therapy of the entity is usually discussed with relationship to this organism.

*Therapeutic Outline*²³

1. Discontinuance of present antibiotics.
2. Specific antistaphylococcal antibiotic therapy.
3. Hydration (I.V. fluid).
4. Blood transfusions to combat shock in severe form.
5. Vasopressors and steroids to combat shock in severe form.
6. Fecal enemas. Some workers are dubious of the efficacy of this mode of therapy in restoring normal bowel flora. Altemeier indicates that esthetic as well as clinical problems preclude its routine use.
7. *Lactobacillus acidophilus*. This is a normal intestinal inhabitant which has been made resistant to commonly used antibiotics. It helps restore the normal flora and eliminate staphylococcal overgrowth.
8. Paregoric, kaopectate, etc.

Antibiotics

It is well known that as new antibiotics are introduced, several months elapse before resistant strains of *S. aureus* are noted. Such organisms initially appear sporadically and then may finally become established in the hospital depending upon the usage of the antibiotics. Erythromycin and chloromycetin-resistant strains are being encountered more frequently.¹⁸

At present such newer penicillins as sodium oxacillin and methicillin are considered the antibiotics of choice by some workers. Wallace et al.²⁴ report that vancomycin has been uniformly effective in terminating diarrhea and eliminating staphylococci from the stool, usually within 48-72 hours after institution of therapy. The suggested dose is 0.5 gm. p.o. q6h until the diarrhea ceases.

Summary

The pathogenesis and etiology of pseudomembranous enterocolitis remain obscure. Many workers² discuss this disease and staphylococcal enterocolitis as the same entity or as a variant of the same entity. Others strongly advocate a separation of the two into distinct disorders.¹² A review of the literature reveals a frequent association between the pseudomembranous disorder and the recovery of staphylococci from the diarrheal stool. However, the basic mechanism or underlying disorder has not yet been elucidated. Theories in this regard include hypoxia, local vascular defects, increased permeability of the intestinal wall with resulting bacterial invasion. Although staphylococci may be a factor in accentuating or producing some of the cases of pseudomembranous enterocolitis, it does not adequately explain all occurrences.²⁵

Case Report

History

A 50-year-old chronic alcoholic was admitted to the Hennepin County General Hospital for the third time on 4/19/66 with a one-week history of cough and dyspnea. The cough had been productive of greenish sputum for three days prior

The answer may be yes...if they're not on Hygroton. For instance, a therapeutic dose of a short-acting diuretic may cost 3 times as much as an equivalent dose of Hygroton. With Hygroton, in fact, you can usually do the job with just one tablet a day or one every other day. It's no wonder that the trend has been away from short-acting, multiple-dose, high-cost diuretics.

You may hear that a short-acting diuretic was more effective in a 400 mg. (ten-tablet) dose than Hygroton in a 200 mg. (two-tablet) dose.

If one considers maximum recommended doses for each product, tablet for tablet Hygroton was clearly superior. Two tablets of Hygroton were found to produce almost 40% more natruresis and 20% more weight loss than five tablets of the other diuretic.* Note that these are maximum recommended doses!

For effectiveness, economy, and convenience, therefore, Hygroton is the diuretic to choose to start with and the one to stay with.

*Brest, A. N., et al.: J. New Drugs 5:329, 1965.

Natruresis above control values after maximum recommended doses (mEq./24 hours) in "normal" patients	
111	152
5 tablets short-acting nonthiazide diuretic	2 tablets Hygroton
48-hour weight loss after maximum recommended doses in edematous patients with congestive heart failure due to arteriosclerotic or rheumatic heart disease	
1.84 lbs.	2.2 lbs.
5 tablets short-acting nonthiazide diuretic	2 tablets Hygroton

Indications: Hypertension and many types of edema involving retention of salt and water.

Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.

Warning: With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.

Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH,

or digitalis. Salt restriction is not recommended.

Side Effects: Dizziness, weakness, nausea, vomiting, hyperglycemia, hyperuricemia, headache, muscle cramps, postural hypotension, constipation, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin reactions, including urticaria and purpura, epigastric pain, or G.I. symptoms after prolonged administration.

Average Dosage: One tablet (100 mg.) with breakfast daily or every other day.

Availability: Tablets of 100 mg. in bottles of 100 and 1000. For full details, see the complete prescribing information. 6524-V(B)

HY-4736S

to admission but had changed to rusty color the day of admission. Because of increasing respiratory difficulty he came to the Emergency Dept. for admission.

Significant past history included hospitalization at Glen Lake Sanatorium in 1962 for active pulmonary tuberculosis.

Physical examination revealed a tremulous, elderly white male in moderate respiratory distress. Temperature was 101.8 rectally. Blood pressure 100/70. Pulse 180. Chest, dullness to percussion at right base, inspiratory rales at right base. Abdomen unremarkable. Rectal examination unremarkable. Skin, marked subcutaneous emphysema in the head and neck region.

Laboratory Data

Chest x-ray, massive right lower lobe infiltrate, pneumomediastinum and small left pneumothorax. EKG, supraventricular tachycardia. Sputum smear, gram-positive diplococci. Sputum culture, pneumococci. Blood culture, pneumococci. Hemoglobin 15.0; white blood count, 12,300; 96% neutrophils; 4% lymphocytes.

Hospital Course

Because of a penicillin allergy, therapy was initiated with erythromycin, 500 mgm. I.V. q6h. He remained strikingly dyspneic and acutely ill. A chest catheter was inserted to alleviate the small pneumothorax, but there was no significant improvement. On the fourth hospital day the patient vomited and became apneic. He responded adequately to intubation and subsequent tracheostomy. Because of the possibility of aspiration, chloromycetin, 500 mgm. q6h I.V., was added to his therapy to provide broader coverage. On the sixth hospital day he began having frequent loose green stools. Two days later he suddenly developed increased respiratory difficulty, fever of 104 degrees, hypotension, abdominal distention, and a venous pressure of 0.5 cm. of water. His urine output decreased from 200 to 300 cc. q4h to 30 cc. q4h. Stool cultures which had been obtained two days previously revealed numerous *Staphylococcus aureus*, coagulase positive, which were sensitive to chloromycetin but resistant to erythromycin. He responded dramatically to vigorous parenteral fluid therapy. During succeeding days he continued to excrete large quantities of turbid green stool. A repeat culture revealed staphylococci which were resistant to chloromycetin and erythromycin. Therapy consisted of parenteral fluids, including plasma and whole blood; fecal enemas, *Lactobacillus acidophilus*, vancomycin orally, keflin parenterally, and discontinuance of erythromycin and chloromycetin. The patient gradually improved, such that treatment for the gastrointestinal difficulty could be discontinued by the 13th hospital day. During the remaining two weeks of hospitalization, attention was devoted to the treatment of his lung disease. There was no recurrence of the gastrointestinal symptoms. Repeat stool cultures revealed no pathogens. He was discharged and is being followed in the outpatient department.

Two things we ought to learn from history: one, that we are not in ourselves superior to our fathers; another, that we are shamefully and monstrously inferior to them, if we do not advance beyond them. — T. Arnold

Book Reviews

What sculpture is to a block of marble, education is to the human soul. The philosopher, the saint, the hero, the wise, and the good, or the great, very often lie hid and concealed in a plebeian, which a proper education might have disinterred and brought to light. — Addison

MEDICAL PHARMACOLOGY, PRINCIPLES AND CONCEPTS — 3rd Edition, By Andreas Goth. Publication date: January 25, 1966, The C. V. Mosby Co., \$12.50.

This book suffers from its virtues. The author aims to provide a "concise text containing the principles and concepts of modern pharmacology" in a book "of modest size." He achieves saving of space by "selectivity and conciseness," and he tries to avoid the danger of "too many details which may obscure for the student or practitioner what is really exciting about those areas of pharmacology that are expanding and are contributing greatly to modern medicine."

For the practitioner who is interested in one of the areas discussed in this book, the concise presentation permits him to gain a good knowledge of the clinical pharmacology in that area. Eleven sections of the book are entitled: (1) General Aspects of Pharmacology, (2) Drug Effects on the Nervous System and Neuroeffectors, (3) Psychopharmacology, (4) Depressants and Stimulants of the Central Nervous System, (5) Anesthetics, (6) Drugs Used in Cardiovascular Disease, (7) Drug Effects on the Gastrointestinal Tract, (8) Drugs That Influence Metabolic and Endocrine Functions, (9) Chemotherapy, (10) Poisons and Antidotes, and (11) Prescription Writing and Drug Compendia. The presentation in each section is "concise", but a bibliography for each chapter contains a grouping of recent review articles so that the interested reader can find more detailed information if he has need. The reviewer's concern, however, may be unwarranted; for demand of a second and now a third edition of this book by students and practitioners suggests that many of them agree with the author's statement that "conciseness is a necessity — for a book that is to be used by over-burdened students and physicians." In a field as vast as clinical pharmacology conciseness in writing is a necessity for all authors, and the real choice is between selective and attempted comprehensive presentations. If the choice is "selective" and the areas of interest lie within this book, the purchaser will be satisfied. If not, there is always Goodman and Gilman.

Minneapolis, Minnesota

PROGRESS IN CLINICAL CANCER — Irving M. Ariel, M.D., Grune and Stratton, New York-London. 375 pages, \$15.75.

Ariel has again accumulated an excellent set of manuscripts dealing with the advances in clinical cancer. In that the book is dedicated to Owen H. Wangenstein, most of the authors have been previous students of his who are now scattered from the east coast to the west coast.

Some of the new techniques of diagnosis, surgery, and irradiation are interesting and enlightening phases of this monograph. Though this book would be of interest to the advanced student, it serves its best purpose for the surgeon who is interested in the problem of tumors, their diagnosis and treatment.

Carl O. Rice, M.D.
Minneapolis, Minnesota

CURRENT PRACTICE IN ORTHOPAEDIC SURGERY — September 1966, Volume 3. Adams, C. V. Mosby, \$18.75.

The third volume of this rather compact and well-constructed text differs somewhat from the previous two volumes in that it is slanted even more to topics of pure orthopaedics. A new section on history adds interest to the book. The second section relates to the application of certain orthopaedic procedures in the management of patients with cerebral palsy. The last section is on general orthopaedic procedures, including a very scholarly dissertation on the use of multiple pins in femoral neck fractures and the importance of two-plane reduction, total impaction, and absolute fixation.

The subject matter is well written, although improvement could be made in the anatomical illustrations; fortunately, they are few. The book should appeal to the resident in orthopaedics and to the specialist himself.

Minneapolis, Minnesota

INFLAMMATION: A cellular fight for life

A SYNTEX REPORT based on recently developed hypotheses about topical corticosteroids, including the cellular theories of inflammation by Thomas F. Dougherty, Ph.D., University of Utah.

You are looking at a fibroblast fighting for life. This cell—one of the most common found in connective tissue—has literally been poisoned by cytotoxins released from other cells that have ruptured. Soon, if the abnormal activity of this fibroblast does not cease, it, too, will rupture and die—one more casualty in the inflammatory wave of destruction precipitated by injury.

Until a short time ago no one had ever witnessed such a scene at the cellular level. Now, through advanced cinemicrographic techniques, it is possible to view and photograph the inflammatory process as produced experimentally in living animal tissue. This method permits new insight into the mechanism of inflammation and the role of corticosteroids in therapeutic management. Equally important, these techniques shed new light on factors that may make one corticosteroid more effective than another—factors that can be correlated with other chemical, biologic, and clinical parameters.

Visual evidence of how corticosteroids influence the inflammatory reaction

Working with phase-contrast cine-micrography on living animal tissue, Doctors Thomas F. Dougherty and David Berliner of the University of Utah College of Medicine have actually filmed cellular events that occur during the inflammatory reaction. This remarkable study* and additional work by these investigators, as well as by others, have established a new theoretical biologic basis for the antiinflammatory effect of the corticosteroids. (It must be noted that other theories, such as the lysosome or so-called "suicide bag" theory, have been postulated, although it is quite likely that there are more similarities than differences among the various theoretical models.)

The inflammatory wave of destruction

In this investigation an injurious injection of gelatin is used to set off an inflammatory reaction in living mouse tissue. What follows is a wave of destructive cellular activity that comprises the inflammatory response to injury. Mast cells (which contain heparin, serotonin and histamine) take up water, swell and rupture, releasing their contents, which are toxic outside the mast cell wall. These toxins, in turn, cause disintegration of other cells (such as fibroblasts) and the release of additional toxic material. Capillaries, too, take up water and leak unformed blood elements, causing edema. And polymorphonuclears, lymphocytes and perithelial cells invade the inflamed site. As a result of all these changes, the cellular environment reaches a state of turmoil.

Phase-contrast microscopy showing mast cell before injury.

Mast cell (after injury) has broken up and released cytotoxins.

How corticosteroids change the picture

Corticosteroids appear to virtually stop the abnormal cellular activity that constitutes the inflammatory reaction. This permits the body's natural resources to clear up the inflamed area and repair the damaged tissue. This interpretation is supported by the fact that when the injurious gelatin solution is injected simultaneously with a corticosteroid—Synalar (fluocinolone acetonide)—the inflammatory pattern simply does not develop.

Fibroblast in high state of activity, much distorted.

Mast cells showing effects of corticosteroid action: cells are normal in size, shape and activity.

In summarizing his study Doctor Dougherty states: "...we also feel this work may explain why one corticosteroid helps a patient more rapidly and effectively than another. If it does, it is because one corticosteroid is the fastest, most effective inhibitor of the series of inflammatory events at the tissue level."

*A New View of Corticosteroid Action in Inflammatory Dermatoses, a film based on this study, is now available from your Syntex representative.

How advances in chemical design have achieved greater steroid potency

The chemical modification of corticosteroid molecules from the advent of hydrocortisone to the development of Synalar (fluocinolone acetonide) is a prime example of how biochemists can "design" to increase therapeutic activity and minimize undesirable side actions. Below, for example, we see the important changes that were made in reference to the hydrocortisone molecule to produce fluocinolone acetonide, one of the most active of all topical corticosteroids. As a result, a 0.01% preparation of Synalar (fluocinolone acetonide) has been reported to do the work of a 1% hydrocortisone product containing 100 times more corticosteroid. And it can often do it more effectively.

Hydrocortisone

Fluocinolone Acetonide (Synalar)

- ☐ a double bond between carbons 1 and 2
- ☐ fluorine substitutions at both the 6- α and the 9- α positions
- ☐ the addition of the acetonide at the 16- α , 17- α positions, thus providing one of the most potent topical corticosteroids available.

How bioassay tests are used to "predict" therapeutic potential

Biologic assays are another tool used by researchers to help establish the relative activity of corticosteroids. To date no single method of assaying corticosteroid activity has emerged as the ideal "yardstick" for predicting therapeutic potential. Taken together, however, these methods have proved useful. When such tests are run on various corticosteroids, a definite order of corticosteroid activity becomes evident. Compounds with the highest order of activity may be expected to merit clinical trial to establish their high therapeutic potential. When assayed by these methods, fluocinolone acetonide (Synalar) emerges as one of the most active topical corticosteroids, milligram for milligram, available for clinical application today.

THE THYMUS INVOLUTION ASSAY¹⁻⁴ is run on adrenalectomized rats. The sizes of the glands are measured, and the degree of involution caused by the steroid is determined as an indication of its potency. In the above photo, the comparative involution of thymus glands achieved with hydrocortisone and Synalar (fluocinolone acetonide) is shown. Untreated controls (A) show normal size. Group B— injected with 1, 2 and 4 mg. of hydrocortisone—show progressively smaller thymuses as does Group C— injected with fluocinolone acetonide—but with only 1/500th the dose of hydrocortisone.

THE ANTIGRANULOMA ASSAY¹⁻⁴ also utilizes adrenalectomized rats. Granulomas are induced by subcutaneous implantation of cotton pellets on either side of the thorax. The degree of granuloma inhibition achieved by a steroid reflects its potency. The above photo shows the inhibition of granuloma formation achieved with hydrocortisone and Synalar (fluocinolone acetonide). Untreated controls (A) show large, red granulomas adhering to the pellets. Group B, receiving hydrocortisone and Group C, receiving fluocinolone acetonide, show little, if any, granuloma formation. Fluocinolone acetonide produced the same effect as hydrocortisone with only 1/500th the dose. This assay, as well as the thymus involution assay, measures systemic rather than topical corticosteroid activity. Nevertheless, results by these methods correlate well with other assays and with the milligram potencies of topical steroids in current clinical use.

Worldwide clinical experience confirms the predictable therapeutic potential of Synalar

It is particularly gratifying that the promise of the advanced chemical design and high order of bioassay activity of Synalar (fluocinolone acetonide) has been confirmed by widespread therapeutic application. Indeed, the impressive clinical response rate of Synalar has been documented in no fewer than 232 papers from 22 countries.

PRESCRIBING INFORMATION

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; *for emollient effect:* Ointment 0.025%, 15 Gm. tubes; *for maintenance therapy:* Cream 0.01%, 15 and 45 Gm. tubes, 120 Gm. jars; *for intertriginous or hairy sites:* Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; *for infected inflammatory dermatoses:* Neo-Synalar® Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

CONTRAINDICATIONS: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. **Contraindicated** in individuals with a history of hypersensitivity to any of the components. **PRECAUTIONS:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for pro-

Representative Clinical Results with Synalar*

†Expressed by the authors as excellent, very good, good, complete remission of inflammation, etc.

longed periods of time. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. When severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. **SIDE EFFECTS:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. The neomycin in Neo-Synalar Cream rarely produces allergic reactions.

Venereal Disease A Serious National Problem, Says AMA

Venereal disease is spreading so rapidly that it now represents this nation's most urgent communicable disease problem.

VD is hitting particularly hard among teenagers and young adults, according to the American Medical Association.

The venereal diseases are infecting about two Americans a minute—3,000 a day, or 1,100,000 a year. Cases of infectious syphilis have almost tripled in this country in the past five years. More than a million

new cases of gonorrhea are developing annually.

VD can blind, cripple, and even kill.

The ravages of venereal diseases are all needless tragedy, says the AMA, because both syphilis and gonorrhea can be avoided. If contracted, they can be cured by prompt medical treatment.

The cure for both diseases—penicillin—has been available since 1943. Any family physician or public health clinic can administer

prompt treatment.

Venereal disease is caused by intimate personal contact.

Complacency, ignorance, and a free-and-easy attitude toward moral standards are partly responsible for the spread of VD; the increasing use of alcohol, especially among young people, also plays a role.

Authorities believe, however, that thousands of young people simply aren't aware of the dangers of VD. Once infected, they are complacent about treatment.

One of the first signs of syphilis may be a painless, ulcerating sore. Gonorrhea produces inflammation of the genital and urinary tracts, and a discharge of pus.

A person may contract syphilis and be unaware that he has the disease. After the first symptoms, the germs may remain hidden in the body for as long as 20 years before any damage is discovered. Then the person may become crippled, develop heart disease, blood vessel disease, blindness, or show mental symptoms. Even death may result from this hidden stage of syphilis.

If left untreated, gonorrhea may be responsible for arthritis, endocarditis, sterility, and blindness.

If a person suspects he may have contracted venereal disease, he should go to a physician immediately.

VD should be treated promptly by a physician.

Abstracts, Briefs and Commentaries

PROLONGED HYPOGLYCEMIA

Two instances of prolonged hypoglycemia precipitated by acetohexamide (Dymelor) in patients with renal failure are reported. In one case, the hypoglycemia persisted for eight days after withdrawal of the drug. Renal retention of acetohexamide metabolites possessing hypoglycemic properties appeared to be responsible for the hypoglycemia. Other published reports are summarized. The author concluded that three mechanisms might explain the prolonged hypoglycemia: (1) decreased glycogen storage secondary to liver disease or starvation, (2) renal damage, or (3) insulinoma. The cause for such an exaggerated effect of the drug is not always apparent.

INSULIN-INDUCED HYPOGLYCEMIA

The doctrine that "hypoglycemia begets hyperglycemia" and that excessive doses of insulin are the major cause of instability of diabetes is examined critically in this study.

Four diabetic patients were given 100 gm. of glucose one hour after receiving their usual dose of insulin, and blood sugar values were measured at 30-minute intervals for the subsequent three hours. This procedure was duplicated on another day except that hypoglycemia was produced by the injection of crystalline insulin during the hour before the ingestion of glucose. The impairment of tolerance was no greater following hypoglycemia than during the control observation.

In ten patients, hypoglycemia was produced during the forenoon and recovery was permitted only by the ingestion of the scheduled noon meal. Frequent blood sugar measurements showed no greater postprandial levels than on control days.

The authors conclude that single episodes of hypoglycemia have no significant effect on subsequent blood sugar concentrations when dietary intake is maintained constant. The possibility that frequent repeated

Continued

hypoglycemic episodes could have an adverse effect on the control of diabetes is not excluded.

ENZYME STRIP METHOD OF BLOOD GLUCOSE DETERMINATION

Blood glucose levels were determined by an enzyme strip test and by an AutoAnalyzer method in 542 samples. The enzyme strip test tended to overestimate glucose values in the lower ranges and to underestimate them in the upper ranges. A study of the sources of variability showed that the color-matching step appeared to be the source of most of the technical error. The coefficient of variation of independent determinations on 10 samples by four technicians was 27.5%.

The authors conclude that the clinical usefulness of the test is limited and that it should not be used if other methods of determining glucose levels are readily available. These findings, in general, coincide with those published in several British journals. On the other hand, these strips have considerable value in emergency situations, particularly in helping the clinician to distinguish between hypoglycemic and diabetic comas or in distinguishing symptoms of an anxiety attack from those of hypoglycemia. However, the authors specifically state that the strips should not be used for detecting hypoglycemia.

TOLBUTAMIDE (ORINASE) FOR TREATMENT OF DIABETES

These authors present the results of nine years' experience with tolbutamide (Orinase) in the treatment of diabetes. They studied 3,387 patients over periods of up to nine years. There were 526 "primary" failures and 202 "indeterminate" failures; 104 of their patients received tolbutamide in combination with other hypoglycemic agents. Among the remaining 2,555 patients, control was satisfactory for at least one month, but 499 of these (approximately 20%) later were not controlled satisfactorily by the tolbutamide and thus were termed "secondary failures." These secondary failures occurred at the rate of approximately 25% per year.

Only about 10% of the patients starting on tolbutamide were known to be taking the drug six to nine years later. Side-effects were few and relatively benign, taking the form of minor skin eruptions and gastrointestinal disturbances which would clear when the drug was discontinued.

There were three instances of blood dyscrasia which could be attributed with reasonable certainty to the tolbutamide. These included thrombocytopenic purpura, nonthrombocytopenic purpura, and neutropenia; these were documented in each instance by tests for circulating antibodies, and in each instance discontinuance of the drug resulted in recovery. No mention was made in this study of the rather common tolbutamide-

induced intolerance to alcohol. Three instances of hypoglycemia were noted.

The authors conclude that tolbutamide and similar agents are valuable adjuncts to the diet therapy of diabetes, although they do have disadvantages in the form of the high secondary failure rate, the possibility that some patients may not regard their problem of diabetes with as much respect as if they were taking insulin, and the frequent reluctance of the patient to accept daily insulin injections later if these should become necessary.

DIABETIC COMA

Twelve instances of coma, occurring in ten diabetic patients and characterized by hyperosmolality and absence of ketosis, are described. The hyperosmolality (>350 mOsm/liter) was the result of either extreme hyperglycemia (936 to 3,120 mg/100 ml. of blood) or hyponatremia (136 to 156 mEq/liter of serum), or of both. The coma itself appeared to be a consequence of the hyperosmolality and cellular dehydration.

This syndrome occurs most often in the elderly person with mild diabetes. The increased blood sugar level usually responds rapidly to doses of insulin which would ordinarily not be adequate for the usual (ketoacidotic) diabetic coma. In some instances, however, several thousand units may be needed. Correction of the hyperosmolality requires administration of large amounts of hypotonic fluids parenterally. Perhaps the most readily available is 0.45% ("half-strength physiologic") saline, but the composition of fluids to be administered should be determined by the chemical findings in the blood at the moment. Potassium is generally needed, as in ordinary diabetic coma.

Epileptiform symptoms were common and were attributed to the extreme hemoconcentration and viscosity of the blood in older patients who already had compromised cerebral vasculature. In two cases, the hematocrit value was more than 90% and the blood resembled syrup.

Seven of these patients died. In the majority of cases, death could not be ascribed solely to the diabetic state but rather to severe complicating disease.

This syndrome characteristically develops rapidly in elderly persons who have mild diabetes, and often there is no apparent reason for the dehydration. Other associated illnesses may appear to provoke these episodes. Similar findings may be encountered with severe burns and with induced hypothermia in nondiabetics, particularly after administration of generous amounts of glucose parenterally. Extreme hyperglycemia without ketosis may complicate hemodialysis when high glucose concentrations in the dialyzing bath are used to reduce edema.

Extreme hyperglycemia and hypertonicity appear to be hazards in themselves. The clinician should be aware of these syndromes and be prepared to carry out appropriate treatment.

ABDOMINAL ANEURYSM

Operative and nonoperative cases of abdominal aortic aneurysm were studied to determine the effect of resection on long-term survival. Included in the survey were 480 operative and 223 nonoperative cases. The two groups were standardized into subgroups as to age over 70 years, systolic blood pressure over 150 mm. Hg., cardiac status of II, III, IV, blood creatinine level over 2 mg. %, and significant pulmonary disease.

Cumulative survival statistics of the two groups were obtained and curves plotted. Using actuarial methods it was found that removal of the aneurysm with graft replacement approximately doubled the life expectancy.

COMMENT: This is a detailed study. Although there may be valid criticism as to the method used in setting up the study, the striking fact remains that the percentage of deaths by rupture in the nonoperative series is far greater than the percentage due to operative mortality in the comparative group.

ELASTOFIBROMA

Pathological curiosities continue to sprout in unexpected places. Pathologists did not identify the elastofibroma, a benign soft tissue tumor of subscapular space, until 1961. Now the reports of Barr and of Brown and his colleagues bring the total of reported cases to eleven.

Barr's communication lists three patients: a forty-five-year old woman with bilateral elastofibromas which occurred four years apart, a sixty-two-year-old woman with a lesion beneath the scapula, and a seventy-five-year-old man with a tumor over the trochanter of the femur. The man's lesion represents the first known instance of an elastofibroma occurring outside the confine of the subscapular space. The report of Brown et al. concerns a fifty-eight-year-old female native of the Ryukyu Islands. She had a 95 by 7 by 6 cm. mass beneath the scapula. The pathogenesis of these curious lesions is uncertain, but they may represent elastotic degeneration of collagen rather than true elastic tissue.

Bay Leaves

Bay tree leaves help palsies, convulsions, cramps, aches, tremblings and numbness in any part, weariness also, and pains that come by sore traveling. They wonderfully help all cold and rheumatic distillations from the brain to the eyes, the consumption, old coughes, shortness of breath, and thin rheums.

Nicholas Culpeper

In Memoriam

There are treasures laid up in the heart, treasures of charity, piety, temperance, and soberness. These treasures a man takes with him beyond death when he leaves this world. — Buddhist Scriptures

EDGAR R. SATHER, M.D.

Dr. Edgar R. Sather, 77, prominent Alexandria physician, died December 14, after a short illness. Born in Willmar, Dr. Sather was a graduate of the Iowa State Medical School.

He was a past president of the Park Region Medical Society, a past vice president of the Minnesota State Medical Association and a present member of its Physicians' Assistance Committee, former chief-of-staff of the Douglas County and Our Lady of Mercy hospitals and a member of the American Medical Association. Dr. Sather was also a 50 Club and Life member of the Minnesota State Medical Association.

He is survived by his wife, a daughter and a son.

ARTHUR L. KUSSKE, M.D.

Dr. Arthur L. Kusske, 82, New Ulm physician, died December 31, after a brief illness. Born in Sibley Township, Dr. Kusske received his medical degree from the University of Illinois. He started to practice in Sanborn, Minnesota, in 1907 and for several years made his country calls by horse and buggy. He bought the second automobile sold in Sanborn. Later he practiced in Hutchinson, Minnesota, becoming a specialist in eye, ear, nose and throat.

He was a member of the Brown County Medical Society and American Medical Association and a Life and 50 Club member of the Minnesota State Medical Association.

He is survived by his two sons, Doctors Douglas and Bradley Kusske, eye specialists in St. Paul.

VICTOR M. VAUGHAN, M.D.

Dr. Victor Vaughan, 68, Truman physician, died January 26. Born in Blooming Prairie, Minnesota, Dr. Vaughan graduated from the University of Minnesota Medical School.

He was a member of the Blue Earth Valley Medical Society, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife and one son.

ERNEST A. OLSON, M.D.

Dr. Ernest Olson, 67, Pine Island physician, died January 23. Born in Franklin, Minnesota, Dr. Olson obtained his medical degree at the University of Minnesota Medical School.

In 1965 he was honored by Pine Island on occasion of his having served that community for forty-one years. He was a former president of the Zumbro Valley Medical Society, long-time member of the House of Delegates of the Minnesota State Medical Association, member of the Southern Minnesota Medical Association, American Medical Association, Minnesota Academy of General Practice, and the American Academy of General Practice. He was also on the staffs of the Zumbro Hospital and Olmsted Community Hospital in Rochester.

He is survived by his wife.

ROBERT W. HOLMEN, M.D.

Dr. Robert W. Holmen, 60, St. Paul Otolaryngologist, died February 10. Born in Minneapolis, Dr. Holmen graduated from Gustavus Adolphus College and the University of Minnesota Medical School. After six years in general practice, he entered upon his specialty in otolaryngology and ophthalmology after completing graduate work at the University of Minnesota. He has practiced medicine in St. Paul continuously since 1932 until September of 1966 when he was stricken with his last illness.

He was a director of the Northwest American Medical Association, a member of the Ramsey County Medical Society, American Medical Association, Minnesota State Medical Association and the Academy of Otolaryngology and Ophthalmology. He was on the boards of managers of Bethesda Hospital and the Invalid Home.

Dr. Holmen in addition to his medical practice gave enormous amounts of time to the work of his church. He was a member of the Board of Directors of the Christian Service of the Lutheran Minnesota Conference also serving on many boards, committees and organizations in his church.

He is survived by his wife, a daughter and two sons. His son Douglas is presently stationed in the Middle East with the U. S. Naval Reserve Medical Corps.

TABLETS

Equagesic[®]

(meprobamate and
ethoheptazine citrate with
aspirin)

Precautions: Keep out of reach of children. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. Withdraw gradually after prolonged high dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance. If drowsiness, ataxia or visual disturbances occur, reduce dose. If symptoms persist, caution patients against operating machinery or driving. Give cautiously to patients with suicidal tendencies. Treat attempted suicide with immediate gastric lavage and appropriate supportive therapy.

Side Effects: Ethoheptazine and aspirin may occasionally cause nausea, vomiting, epigastric distress, and rarely dizziness and CNS depression. Overdosage may result in salicylate intoxication. Meprobamate rarely causes allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioedema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Rarely, cases of aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported; almost always, in the presence of known toxic agents.

Contraindications: History of sensitivity or severe intolerance to aspirin or meprobamate.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.
Wyeth Laboratories Philadelphia, Pa.

Weighing on his mind, too

When pain evokes anxiety and tension, thereby heightening patient discomfort, a simple analgesic may only touch on part of the problem.

This single-prescription, non-narcotic product, however, usually provides effective analgesia *and* helps put the patient's mind at ease.

special formula for a special problem

*specifically formulated
for symptomatic
relief of sinus headache*

Sinus headache is not a single entity, but a chain reaction of pain. It is facial pain—deep, dull, aching and nonpulsating. It is referred pain—originating in the nose and sinuses but felt at another site. It may become generalized pain and tension in head and neck. It is one or all of these.

The Sinutab formula is designed for symptomatic relief of sinus headache.

It provides two analgesics to relieve pain and discomfort...an effective oral decongestant to reduce mucosal congestion... and an antihistamine to help control allergic manifestations.

Side Effects: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

WARNER-CHILCOTT
Morris Plains, N.J.

SINUTAB[®] for sinus headache

Norinyl[®] tablets

(norethindrone 2 mg. $\bar{c}$ mestranol 0.1 mg.)

for multiple contraceptive action that has produced a record of unexcelled effectiveness

**inhibition of ovulation by means of
2 time-proved hormonal agents**

**production of a cervical mucus hostile to
sperm motility and vitality**

**creation of an endometrium unreceptive
to egg implantation**

no unplanned pregnancies

Norinyl provides multiple action for maximum assurance of success. It does not depend on ovulation inhibition alone for contraceptive effectiveness. The mechanism of action of combined hormonal therapy results in ovulation inhibition reinforced by other protective mechanisms, including a hostile cervical mucus¹⁻¹³ and an acceleration of endometrial changes.^{1-3,7-16} With Norinyl, no unplanned pregnancies have been reported to date when used as directed.

plus important supportive benefits that help her through those critical early months of oral contraception

low incidence of side effects

Low incidence of BTB and spotting, nausea and amenorrhea tends to minimize side effect problems and increases patient cooperation.

no confusion about dosage

An unbreakable "confusionproof" package makes it easy to adhere to prescribed dosage schedule: individually sealed tablets numbered from 1 through 20 *plus* monthly calendar record enables patient to double-check dosage intake by day and corresponding tablet number.

Contraindications: Thrombophlebitis or pulmonary embolism (current or past). Existing evidence does not support a causal relationship between use of Norinyl and development of thromboembolism. While a study which was conducted does not resolve definitively the possible etiologic relationship between progestational agents and intravascular clotting, it tends to con-

firm the findings of the Ad Hoc Advisory Committee appointed by the Food and Drug Administration to review this possibility. Cardiac, renal or hepatic dysfunction. Carcinoma of the breast or genital tract. Patients with a history of psychic depression should be carefully studied and the drug discontinued if depression recurs to marked degree. Patients with a history of cerebral vascular accident.

Warning: Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn.

Precautions: By May 1963, experience with norethindrone 2 mg.—mestranol 0.1 mg. had extended over 24 months. Through miscalculation, omission or error in taking the recommended dosage of Norinyl, pregnancy may result. If regular menses fail to appear and treatment schedule has not been adhered to, or if patient misses two menstrual periods, possibility of pregnancy should be resolved before resuming Norinyl. If pregnancy is established, Norinyl should be discontinued during period of gestation since virilization of the female fetus has been reported with oral use of progestational agents or estrogen. When lactation is desired, withhold Norinyl until nursing needs are established. Existing uterine fibroids may increase in size. In metabolic or endocrine disorders, careful clinical preevaluation is indicated. A few patients without evidence of hyperthyroidism had elevated serum protein-bound iodine levels, which in the light of present knowledge, does not necessarily imply hyperthyroidism. Protein-bound iodine increased following estrogen administration. Bromsulphalein retention has occurred in up to 25% of patients without evidence of hepatic dysfunction. Studies from 24-hour urine collections have shown an increase in aldosterone and 17-

ketosteroids and decrease in 17-hydroxycorticoid levels. Thus, Norinyl should be discontinued prior to and during thyroid, liver or adrenal function tests. Because progestational agents may cause fluid retention, conditions such as epilepsy, migraine and asthma require careful observation. Thus far no deleterious effect on pituitary, ovarian or adrenal function has been noted; however, long-range possible effect on these and other organs must await more prolonged observation. Norinyl should be used with caution in patients with bone, renal or any disease involving calcium or phosphorus metabolism. Side Effects: Intermenstrual bleeding; amenorrhea; symptoms resembling early pregnancy, such as nausea, breast engorgement or enlargement, chloasma and minor degree of fluid retention (if these should occur and patient has not strictly adhered to medication plan, she should be tested for pregnancy); weight gain; subjective complaints such as headache, dizziness, nervousness, irritability; in a few patients libido was increased. In a total of 3,090 patients, 2.2% discontinued medication because of nausea.

NOTE: See sections on contraindications and precautions for possible side effects on other organ systems.

Dosage and Administration: One Norinyl tablet orally for 20 days, commencing on day 5 through and including day 24 of the menstrual cycle. (Day 1 is the first day of menstrual bleeding.)

Availability: Dispensers of 20 and 60 tablets; bottles of 100.

College Yield to Stay High, If Business Helps

It's called one of the shrewdest investments business ever made—the college contribution. It has paid the best dividends business ever got—the 42% of college-educated leaders that business employs, every year.

A real human potential. Leader stuff. Bright with brainpower, brimming with skills. Able to fill management posts.

But can it go on, can the colleges guarantee the supply?

Higher education is in

trouble. Costs are skyrocketing. On the average, tuition fees cover only about 1/3 of the educational cost.

What is needed? More business giving. Unrestricted giving. Business can gain even more by raising the quality of education to an all-time high.

If business wants college talent, it must help keep the colleges in business.

Your aid-to-education program is an aid to yourself.

Camping Opportunities

for
the
Child
With
Diabetes
Mellitus*

DONNELL D. ETZWILER, M.D.**
St. Louis Park, Minnesota

SEVERAL YEARS ago we published an article in this Journal describing the Minnesota State Camp for children with diabetes mellitus.¹ Since that time, significant changes and expansion in this program have taken place which should be of interest to physicians practicing in this area.

This is the tenth anniversary of Camp Needlepoint, which was conceived by Mr. Ronald Youngquist of St. Paul, Minnesota, and supported by the Twin Cities Diabetes Association. The size of the camp has increased from an initial 21 children in 1957 to 140 in 1966; unfortunately, again this year, the camp has had to turn away a significant number of children because of limited space. The camp utilizes the facilities of the St. Paul Y.M.C.A. Camp St. Croix, three miles south of Hudson, Wisconsin, overlooking the St. Croix River. Facilities here are rented for a one-week period the latter part of August each year.

The initial purpose of Camp Needlepoint was to provide camping opportunities for children with diabetes, since they are frequently unable to attend other camps. In 1960, however, it was decided the camp would serve two additional functions: (1) to further instruct these children and their parents in the proper care and management of diabetes mellitus; and (2) to permit the camp to serve as a resource tool and enable professional personnel to gain further insight into the nature of this disease process. Over the past few years it has become increasingly apparent that one of the greatest benefits derived from the camp is the opportunity for children with diabetes mellitus to meet and live with other campers with

the same disease. This experience has provided tremendous psychological benefit for these children.

In addition to the camping program at Camp Needlepoint, a wilderness camping program was introduced five years ago. This adventure sends groups of diabetic teen-aged boys, a physician and a guide into the wilderness areas for a seven-day canoeing experience.

Camping

Activities at Camp Needlepoint include all facilities, personnel, and programs utilized by Camp St. Croix during their regular summer program. Campers with diabetes are accepted from nine thru 16 years of age. Each cabin group consists of eight campers, the counselor and an assistant counselor. Most of the camp's male counselors and program directors are provided by Camp St. Croix; however, some of our past campers also serve in this capacity. Acquisition of good female counselors has been relatively easy; this job has appealed particularly to our past girl campers as well as student and graduate nurses. There are many applications for these jobs each summer with a high percentage of returnees year after year. The use of previous campers has many obvious advantages, and we have recently instituted an active counselor-in-training program, which has proven to be of more interest to teen-aged girls than boys.

The Indians

Cabin groupings are selected on the basis of age. The youngest campers, nine to 11 years old, are designated as "Indians," and this becomes the over-all theme of their camping program. These children are introduced to nature lore and crafts involving Indian projects. Evening council fires are held where Indian stories and dances are taught (Figure 1). All of the usual camping activities — swimming, hiking, cook-outs, boating, competitive sports, etc. — are also included in this program.

The Pioneers

Children 11 to 13 years of age are designated as "Pioneers" and their over-all

camping program is oriented accordingly. In addition to the usual activities, this group has cook-outs and overnight camping experiences (Figure 2).

*The Voyageurs**

The oldest group of campers, ages 13 to 16, are "Voyageurs," and they undertake three-day canoe trips, paddling 35 to 50 miles along the St. Croix River. A physician or graduate nurse accompanies each canoe group to assist and supervise diabetic care.

Camp begins on Sunday, and as the children arrive they are immediately registered and assigned to cabins. After an appropriate amount of time, their parents are asked to gather in the main lodge of the camp where the camping program is discussed with them by the Camp Director and the physician in charge. The parents are then acquainted with the camp routine and the nature of their child's diabetic management during his stay. It is also possible to review quickly some of the basic concepts of diabetic care with these parents at this time. The parents are also informed of past clinical studies that have been carried out at camp, and the project proposed for the current session is explained.

Medical Program

Our current medical program constitutes what we feel is ideal care for these children. Establishing a proper therapeutic regime serves not only to maintain these children in good control but also provides them with a rare learning experience. All children are encouraged to participate in a self-care program. Each child is provided with a kit which contains all materials necessary for urine testing and insulin administration. Campers are requested to bring their own syringes in order that they may become more familiar with this equipment. We do use plastic disposable insulin syringes on our overnight camp-outs and also on the canoe trips; these have proven to be very convenient. The schedule of the camp program is shown in Table 1.

The Morning Specimen

At 6:30 a.m. each camper arises and voids a first specimen which is discarded, and 15 to 20 minutes later a second sample of urine is obtained. It is this specimen that is tested, since it is felt that it more truly reflects the current level of glucose in the blood. This specimen is tested with the assistance of the cabin counselors if necessary; most children, however, are very adept at doing and reading urine tests. In the cabins for younger campers all results are checked by the counselor. Each camper then marks the results of his urine test on the record card which he keeps.

Insulin Requirement

As soon as this procedure is finished, the camp physician sits down with the camper and very quickly goes over the past urine records and, with the assistance of the camper, comes to a decision concerning the amount of insulin required. As soon as this is determined, the physician moves to the

TABLE 1

Daily Schedule	Camp Needlepoint
6:30	Reveille.
6:30-7:00	Urine testing.
7:00-8:00	Insulin administration.
8:00	Flag raising.
8:05	Breakfast.
8:45-9:30	Cabin clean-up.
9:30-12:00	Unit activities and program— craft, nature, athletics, hikes, etc.
10:00	Indian instructional swim.

Continued

next camper. A registered nurse is then available to assist each camper in the preparation of his injection. For campers who routinely give their own insulin, the nurse merely checks the dosage, observes and reviews techniques. Campers who do not give their own injections but indicate some interest are taught by our nurses. We do not force campers to give their own injections; however, the social pressure in each cabin is sufficient in most cases to arouse these children's interest in self care (Figure 3). The opportunity to see and work with each camper individually each day has provided us with an excellent opportunity to teach on an effective and informed basis. The physician has a chance to explain why urine tests are important and how they relate to management. The possible effect of the day's planned activities are noted and a prophylactic approach to control is introduced.

The Difficult Diabetic

Urine tests are conducted four times each day — before each meal and at bedtime. Any child who has a 4+ test for sugar is required to test for acetone. Campers with acetone are requested to report to the infirmary where the physician appraises the situation. At bedtime all campers come to the dining room where the physician once again reviews each camper's record for the day and makes any necessary alterations in the evening snack. Midmorning and afternoon snacks are provided each day and may vary depending upon camp activities. After lunch each day the nurses, physicians, dietitians and camp director visit various cabin groups and spend 45 minutes to an hour in informal discussion of diabetes and its many aspects. In such a setting, group discussion has proved most beneficial and brings out many questions which would never be asked in a physician's office.

The Diet

All campers are placed on an exchange diet (Figure 4). At the time a camper's application is first submitted, the family is requested to send in the child's dietary prescription along with a list of the previous day's meals. These are then calculated and

compared. According to our head dietitian, Mrs. Rita Olson, this comparison reveals that less than 20% of the diet prescriptions are being followed at home. It is not infrequent that we receive dietary prescriptions that were given three to five years prior to the time these children attend camp. These are obviously inadequate and impossible to follow. Not all campers are familiar with the exchange dietary system when they first arrive at camp; however, it takes only one meal for them to comprehend the nature of the program. Dietary changes are permitted at the request of the camper. In general, we tend to increase all of our campers 200 calories above the diet given at home. This frequently has to be varied at camp, and on the canoe trips we have to increase the intake of calories from 500 to 2000 per day.

Research Activities

The gathering of such a large number of juvenile diabetics in one place at one time has provided an opportunity for us to carry out numerous clinical studies. Part of the lecture for parents on the first day is devoted to informing them of what the research activities will be and the results of previous programs. Rarely have we had a parent request that his child be excluded from these studies. The vast majority of the parents appreciate the work that is being done and realize that it is beneficial not only to their own child but to all other children with this condition. Some parents have even suggested that their non-diabetic children be used as controls.

What the Juvenile Diabetic Knows About His Disease²

The results of this study motivated us to determine what the families of these children knew about diabetes and how their environment might influence this condition. The following year biographic questionnaires were sent to all families, and we conducted a workshop for the parents, at which time tests on diabetes were given along with the Shipley-Hartford Retreat Scale to estimate IQs. The Minnesota Multiphasic Personality Inventory was sent to the parents, and additional questionnaires were sent to

the children's physicians and their school teachers.³

Glucagon in the Juvenile Diabetic

Camp has provided an excellent opportunity to assess the effect of glucagon in the juvenile diabetic; our studies revealed glucagon was highly effective in the juvenile diabetic experiencing hypoglycemia.⁴ Further studies at camp clarified some of the discrepancies appearing in the literature concerning the action of this hormone in juvenile diabetes.⁵

Urinary Tract Infection and Other Studies

The increased incidence of urinary tract infections among older diabetics has recently been disputed. Over a two-year period urine cultures were obtained from our campers, and the results indicated there was no increased frequency of urinary tract infections among these children.⁶ Other studies we have conducted dealt with determination of ocular pressure, blood pressures, funduscopic examinations and photographs, correlations of hypoglycemia and electroencephalographic changes, and comparisons of venous and arterial glucose levels. We feel that these efforts have been beneficial not only to our campers but to many other juvenile diabetics as well.

Psychological Experiences

The psychological value of camps for special illnesses, such as diabetes, is difficult to assess. From personal observation, I believe that most campers are much more willing to accept their disease after being at camp. The chance to work, play and live among others having the same condition is a rare opportunity for these children. In many instances it is the first time they have known other children with the disease, and they no longer feel quite so alone with their problem. At camp the disease is accepted as part of the daily routine and no sympathy is exhibited. They are expected to work, play and behave as any ordinary non-diabetic child would. Perhaps one of the best examples of the influence of group living is shown in an experience we had last summer. The first

morning of camp we found a group of nine-year-old girls gathered around one of their cabin mates who was administering insulin in her abdomen. Six of the eight campers in this cabin did not give their own insulin and seven of them had never seen it given in the abdomen. They were obviously interested in this technique and impressed that the girl was giving her own shot. The next morning all of these girls wanted to give their own insulin injections and insisted that it be given in their abdomens. This was done without any persuasion or suggestion from the staff. The medical staff is there to assist campers in procedures which the campers themselves decide upon.

Wilderness Camping

Our wilderness camping program was established five years ago in order to stimulate our older teenagers. These campers are 15 to 18 years of age and most have gone through our program at Camp Needlepoint. These trips have been either into the wilderness canoe areas in northern Minnesota or into the wilderness area along the Namakagon River in Wisconsin. Meals for these trips have been appropriately planned and all supplies and foods are carried in packs. These packs weigh between 75 and 85 pounds and the canoes weigh somewhere between 85 to 100 pounds. Each boy carries a pack or a canoe on portages. During the trip these boys paddle 200 to 250 miles in seven days (See photo on cover). One of the objectives of this program is to demonstrate to these boys and their families that diabetics who take care of themselves can be placed under rigorous conditions and do well. We have encountered no difficulties with this program; each group is accompanied by a physician and a trail guide.⁷

Conclusion

We believe that these camping programs are greatly beneficial to the young diabetic who so frequently has led a sheltered and extremely regulated life. Camp permits an opportunity to take part in vigorous outdoor living where good diabetic management is demonstrated and carried out, and its importance stressed.

provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered
- * **NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY**
Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN[®] 375

(tetracycline HCl 250 mg.
triacytyleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacytyleandomycin*, a constituent of Signemycin, has been associated with deleterious changes in liver function. See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have known hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacytyleandomycin.

Precautions and Adverse Reactions: *Triacytyleandomycin*, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver

function are reversible after discontinuation of the drug.

Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacytyleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

three times daily.

WILLIAM H. RORER, INC.
Fort Washington, Pa.

Tandearil[®] oxyphenbutazone

Therapeutic Effects: Tandearil is a nonhormonal compound which may rapidly resolve inflammation and help restore normal joint function. Its action does not affect pituitary-adrenal function or impair immune responses. Its value in osteoarthritis is especially noteworthy because this disorder responds inconsistently to steroids and is often resistant to salicylates. Further, indomethacin is limited only to osteoarthritis of the hip, whereas oxyphenbutazone is effective in all forms of the disease.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonyleurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage. Make regular blood counts. Discontinue the drug and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: The initial daily dosage in adults is 300-600 mg. in divided daily doses. When improvement occurs, dosage should be decreased to the minimum effective level; this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

How Much Life Insurance?

VERY FREQUENTLY we are confronted with this question from a client: "How much life insurance should I have?" The client expects an answer in terms of "averages" or some "rule of thumb." True, there are many such "averages" and "rules of thumb" in existence today. Some say that a person should spend approximately 10% of his annual income for insurance. How much insurance will this buy? We all know that \$1,000 may pay the annual premium on a \$15,000 Retirement Income policy, or it may pay the annual premium on \$170,000 of Decreasing Term insurance. The age of the insured and the type of insurance are the deciding factors. Another fallacy in this approach is the assumption that everyone can afford 10% of his annual income for insurance — no more — no less. Obviously, this point needs no explanation; it just isn't true.

A second approach is to try to fix the dollar amount of insurance according to income. Some advocate four to five times annual income. There are many pitfalls in this approach. To use an exaggerated example, this approach would dictate \$300,000 insurance for a doctor, age 55, with single net income \$75,000 and assets of \$450,000. At the other extreme, it would dictate \$80,000 insurance coverage for the 33-year-old doctor earning \$20,000, with a 30-year-old wife and four young children, \$25,000 in debt and with no income-producing assets. In neither case would the doctor have the proper amount of insurance in his portfolio.

What, then, is the answer to the question, "How much life insurance?" In our opinion, there can be no stock answer and no application of "guides" or "rules of thumb." Every such question must be approached from an individual standpoint and answered after a thorough analysis of needs, present insurance, other assets, and finally, the client's ability

to pay the premium load required for such a program.

To approach an individual and personal problem on the basis of the "average" is like the man with his head in the oven and his feet in the freezer — *on the average* he feels just right. Such an approach to our clients' insurance problems would mean that only a scattered handful would have a *right* amount to afford the desired protection; but they all would have an *average* amount.

The following are some basic concepts that we advocate in planning an insurance program:

1. Using a realistic approach and realizing that insurance is a disaster-type protection, write down exactly what you want to provide for your family if you die. How much for debt, education, estate costs, current expenses and monthly income.

2. What will your present resources, including present insurance and all other assets, do toward fulfilling these needs?

3. What insurance is required to satisfy the remainder of your needs? In answering this, your insurance advisor will fill temporary needs with some of the various term contracts available. Permanent needs will probably best be satisfied with a low-cost permanent contract.

4. Finally, is the cost of the additional insurance reasonable and within your budget? If not, needs must be trimmed and/or more term insurance used.

By following this approach, we are not considering our client as an "average" or a "statistic;" we are considering him an individual. In summary, to assure an adequate life insurance program at a realistic cost, use an impartial adviser, take an individual approach, be realistic in weighing your needs and, finally, buy insurance for *protection*, not for investment purposes.

The Stature of Mediocre Men

What makes a nation great is not primarily its great men, but the stature of its innumerable mediocre ones. — Ortega Y Gasset

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Men love to wonder, and that is the seed of our science. — Emerson

Physician's Diary

Intellect marches, but imagination rambles. — Comtesse Diane

Dr. Melvin Sinykin of Minneapolis was elected president of the Minnesota Obstetrical and Gynecological Society. Other officers are: **Dr. Grant Hartnagel**, Red Wing, vice president; **Dr. Peter J. Bartzen**, Duluth, assistant secretary-treasurer, and **Dr. Herschel B. Cope**, Virginia, board member.

* * *

Dr. John T. Kelly was re-elected chief of staff for 1967 of St. Mary's Hospital Medical Staff. **Dr. Berton D. Mitchell** was re-elected vice president and **Dr. Norman F. Stone** was re-elected secretary.

* * *

Doctors **David C. Dahlin** and **Mark B. Coventry** of the Mayo Clinic, Rochester, presented papers in the Scientific Program of the 34th Annual Meeting of the American Academy of Orthopaedic Surgeons in San Francisco in January.

* * *

Dr. N. L. Gault, Jr., associate professor of medicine and associate dean of the University of Minnesota's College of Medical Sciences, participated in the Third World Conference on Medical Education in New Delhi, India.

* * *

Dr. George B. Logan, professor of pediatrics, Mayo Clinic, Rochester, was named vice-president and president-elect of the American Academy of Pediatrics at the Academy's annual meeting.

* * *

Dr. O. Theron Clagett, head of a section of surgery in the Mayo Clinic, Rochester, and professor of surgery in the Mayo Graduate School of Medicine, was elected president of the Western Surgical Association at the annual meeting of the organization in Phoenix.

* * *

NEW LOCATIONS: **Dr. David B. Eaton** joined the staff of the Worthington Clinic. **Dr. Eaton** was formerly on the staff of the University of Iowa Medical School . . . **Dr. Matthew B. Smorstok** of Monticello has joined the staff of the University of Minnesota Health Service in Minneapolis . . . **Dr. Keith D. Larson**, a former Mayo Graduate School

resident in medicine, has been appointed medical director of the Moose Lake State Hospital . . . **Dr. Emmanuel Balcos** of Minneapolis will open up a practice in Morgan in July . . . **Dr. Curtis A. Johnson** is practicing in Waseca . . . **Dr. John Fluegel** has left the Olmsted Medical Group in Rochester to enter specialty training.

* * *

Dr. L. Emmerson Ward, a consultant in medicine of the Mayo Clinic, has been elected to his fourth term as chairman of the Mayo Clinic Board of Governors.

* * *

Dr. Robert A. Good, professor of pediatrics and microbiology at the University of Minnesota Medical School, delivered the annual Louis A. Greensfelder lecture at the Michael Reese Hospital and Medical Center, Chicago, in February. **Dr. Good** spoke on "Development and Involution of the Lymphoid Tissue in Relation to Immunologic Capacity."

* * *

Dr. Marvin M. D. Williams, consultant in biophysics in the Mayo Clinic, Rochester, and professor of biophysics in the Mayo Graduate School of Medicine, was elected vice president of the Radiological Society of North America, Inc., at the annual meeting of the organization at Chicago.

* * *

Dr. Clifford Stadem of Twin Valley was elected president of the Red River Valley Medical Society. Other officers elected were: **Dr. Earl Dagg** of Thief River Falls, vice president, and **Dr. H. D. Clapp** of Crookston, secretary-treasurer.

* * *

Dr. Bruce Douglass has been named president of the Minnesota Academy of Occupational Medicine and Surgery.

* * *

David R. Preston, assistant administrator of St. Mary's Hospital in Duluth, has been named associate director of the University of Minnesota Hospitals, and **John H. Westerman**, associate director of the University of Minnesota Hospitals, became director of the Hospitals in January.

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by
absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylentetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

ged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Geroniazol[®] TT

nicotinic acid 150 mg., pentylenetetrazol 300 mg.
Tempotrol[®] Time Controlled Tablet

I'm supposed to get up and do things?

With my heart?

It's entirely natural—and may even be desirable—for the cardiovascular patient to be somewhat anxious about himself.

But when anxiety leads to unreasonable self-imposed limitations and restrictions . . . when it aggravates cardiovascular symptoms . . . when it interferes with restful sleep, measures to help alleviate the anxiety are probably in order.

One measure, of course, is reassurance. Another, adjunctive measure, is EQUANIL (meprobamate).

Over a decade of experience has shown that EQUANIL (meprobamate) is generally well tolerated as well as effective. Side effects are usually limited to transient drowsiness; serious, therapy-interrupting side effects are rare.

Cautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. After prolonged high dosage, drug should be withdrawn gradually to avoid possibly severe withdrawal reactions including epileptiform seizures. Side effects include drowsiness and, rarely, allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Warn patients of possible reduced alcohol tolerance. Should drowsiness, ataxia, or visual disturbances occur, dose

should be reduced. If symptoms persist, patients should not operate vehicles or dangerous machinery. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Other blood dyscrasias—aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia—have occurred rarely, almost always in the presence of known toxic agents. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. Prescribe very cautiously for patients with suicidal tendencies. Suicidal attempts should be treated with immediate gastric lavage and appropriate supportive therapy.

Contraindications: History of sensitivity to meprobamate.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

American Hospital Formulary Service Category No. 28:16.08

Equanil[®]
(meprobamate)

**How long will it take him
to recover from the flu
if he just doesn't care?**

Does he really care?
Is he alert, encouraged,
positive and optimistic
about getting out of bed
and back to work soon?

Or is he giving in to
the depressing impact
of confinement?

When functional fatigue
complicates convalescence,
Alertonic can help...

Pleasant-tasting Alertonic is pipradrol hydrochloride—an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that so often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

Adequate dosage is important: Prescribe Alertonic—one tablespoonful t.i.d., 30 minutes before meals...tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Alertonic[®]

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B₁) (10 MDR*), 10 mg.; riboflavin (vitamin B₂) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B₆), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.

†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

"George wants to know if it's okay to take his cold medicine now, Doctor, instead of seven o'clock?"

The long-continued action of Novahistine LP should help you both get a good night's sleep. Two tablets in the morning and two in the evening will usually provide round-the-clock relief by helping clear congested air passages for freer breathing. Novahistine LP also helps restore normal mucus secretion and ciliary activity—normal physiologic defenses against infection of the respiratory tract. Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

AMA 116th Annual Convention • Atlantic City, New Jersey • June 18-22, 1967

Come to Atlantic City—one of America's favorite by-the-sea playgrounds—and join your colleagues at the AMA's 116th ANNUAL CONVENTION!

Fine hotels and motels, excellent restaurants, plus all the advantages of a lively resort make this year's Convention a must for you and your family. Atlantic City provides a superb setting for a summer classroom and all the latest techniques of modern medicine. Plan to be one of the participants in this rewarding four day postgraduate education program.

• Four general scientific sessions • 23 section programs • 575 scientific and industrial exhibits. Lectures, panel discussions, motion pictures, and color television. Plan to attend—continue your postgraduate education.

RESERVE NOW for the **SCIENTIFIC AWARDS DINNER** in honor of the Scientific Award Winners—Wednesday, June 21, 1967. Since space is limited, we suggest you make your reservations before June 1, 1967. Tickets are \$10.00 each, payable in advance.

See JAMA May 8, 1967 for complete scientific program—forms for advance registration and hotel accommodations.

INTERNIST AND GENERAL PRACTITIONER wanted to join a four-man clinic group in suburban Minneapolis. Laboratory and X-ray with part-time radiologist. Excellent open hospital staff association. Salary to start with early partnership. Write: MINNESOTA MEDICINE — 372; 496 Lowry Medical Arts Bldg., St. Paul 55102.

WANTED: young internist and pediatrician, board certified or eligible, to join five-man group consisting of three GPs, a general surgeon and a radiologist. College town serving population of 22,000 thirty miles from Twin Cities. Salary open with early partnership opportunity. Write or call collect: Ed Jenkins, Manager, River Falls Medical Clinic, River Falls, Wisc. Phone 425-5322.

DON'T OVERLOOK THIS . . . 3 months' rent free in modern medical clinic — successful location in N.W. suburb of Minneapolis. Come see anytime — 36th and Noble Avenue North. Noble Drug, Ju 8-9449, Ben or Lou.

FOR RENT: Space available for surgical subspecialists. Excellent location. Near Unity Hospital, 10 minutes from Mercy. Share space with General & Thoracic Surgeon and 2 interns. Call Mrs. Winkel — 560-1700, Fridley.

FOR LEASE IN TWIN CITIES — small clinic, large parking area. With lease goes incredibly lucrative general practice, patients' records and excellent staff, at NO FEE. Write: MINNESOTA MEDICINE — 371; 496 Lowry Medical Arts Building, St. Paul 55102.

RESIDENCIES IN PHYSICAL MEDICINE and Rehabilitation offer challenge and opportunity in a growing field. Comprehensive training utilizing Mayo Clinic facilities and faculty, at \$3600 to \$10,000 stipend. Attractive community, excellent school system, cultural advantages. Contact Gordon Martin, M.D., Mayo Graduate School of Medicine, Rochester, 55901.

WANTED: Young general practitioner to join five-man group consisting of three GPs, a general surgeon, and radiologist. College town serving population of 22,000 30 miles from Twin Cities. Also need LOCUM TENENS in general practice. Contact: Ed Jenkins, Manager, River Falls Medical Clinic, River Falls, Wisconsin, Phone 425-5322.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building — 90 miles east of St. Paul — city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

FOR SALE: Mattern x-ray unit K.V.-60. Good for chest and extremity work. Also an examining table, instrument cabinet, E.K.G., and other equipment.

Contact L. A. Whitesell, Jr., M.D. 207 South 1st Street, Buffalo, Minnesota 55313.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE — 289; 496 Lowry Medical Arts Building; St. Paul, 55102.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

WANTED — Internist, board certified or qualified, to associate with two board certified internists. Ten man multi-specialty group. (Lenont Peterson Clinic, Virginia, Minnesota) — Heart of the expanding taconite industry.

GENERAL PRACTITIONER, associate, urgently needed. Unopposed practice established 20 years. 32 bed new hospital with additional 20 bed chronic unit. Good anesthesia coverage, lab. facilities. Excellent clinic one block from hospital. Salary with early partnership. Locum tenens also considered. Call collect 218-782-4725 or write Klefstad Clinic, Greenbush, Minnesota.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE — 365; 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTITIONER — to join established five-man group consisting of three general practitioners, a general surgeon, and an internist. Excellent clinic facilities situated adjacent to the city hospital. Starting salary negotiable. Retirement plan and many other fringe benefits. Call or write: Richard F. Lehigh, Owatonna Clinic, Owatonna, Minnesota 55060. Phone: 451-1120.

CLASSIFIED ADVERTISEMENTS

EXCELLENT OPPORTUNITY for Intern or Resident finishing in June or July to try practice in specialty group on locum tenens basis — June 1 thru August 31, 1967. Replacing Internist on leave of absence. Option of remaining on staff if desired. Salary open. Write or call collect, 281-3184, Northwestern Clinic, Crookston, Minnesota.

GENERAL PRACTITIONER wanted by two-man general practice group. Surgery within capability. Community Hospital. Eligible partnership if preferred. Write: MINNESOTA MEDICINE — 393, 496 Lowry Medical Arts Building, St. Paul — 55102.

RESIDENTS IN PSYCHIATRY — Opening for July 1, 1967. Stipend \$11,400 for physicians just completing internship. Federal stipend of \$12,000 annually with an extra \$3600 tax exemption available to physicians with 4 years non-psychiatric training or experience following internship. Graduates of American schools must be eligible for Iowa licensure. Foreign graduates must have ECFMG certificate. This is an acute treatment hospital with 450 in-patients and large outpatient department, children's unit under direction of Board-certified Child Psychiatrist. Intensive didactic teaching program with rich clinical experience directed toward preparing the resident for Board certification. Thirteen senior staff members including ten Board certified. Numerous consultants authorized for 18 residents. Affiliation with University of Iowa. Enthusiastic training and treatment programs that are best appreciated by a personal visit. Write W. C. Brinegar, M.D., Superintendent or John J. Worthington, M.D., Director of Psychiatric Training, Mental Health Institute, Cherokee, Iowa 51012.

GENERAL PRACTITIONER experienced in general medicine and surgery seeking location in Minneapolis area. Individual or partnership. Write: MINNESOTA MEDICINE — 368, 496 Lowry Medical Arts Building, St. Paul 55102.

REALLY LIVE — ON THE ST. CROIX. Your own retreat. Nearer skiing — dock your boat. Spring Company has several. Contact: Harold Onstad, Marine on St. Croix, call 663-8261.

EXPANDING, UPPER MIDWEST, Multispecialty group; college city, seeks the addition of: Internist, Otolaryngologist, General Surgeon, Radiologist, and Urologist. Unlimited income. Contact: John J. Eustermann, M.D., c/o Mankato Clinic, Ltd., Mankato, Minnesota 560-387-1811.

AVAILABLE for immediate occupancy, modern doctors' offices in the Midway Medical Arts Building, University and Snelling Avenues, St. Paul. A choice Midway location near the new Inter-City Freeway with excellent public transportation available and adequate parking. Contact: Cal Douglas or Len Loftus at 646-7578-St. Paul or write Harold J. Slawik Properties, Inc., 1850 University Avenue, St. Paul.

GENERAL PRACTITIONERS — Lennox, South Dakota has exceptional opportunity available for either single practice or partnership arrangement. Lennox Clinic building available; financial, professional advantages; splendid surroundings in South-eastern South Dakota; large area to serve. Ideal for becoming established. Inquiries, visits welcome. Contact City Mayor Fred Courey, chairman, medical services committee.

"Physician interested in internal medicine wanted for Medical Service. Starting salary \$12,873 to \$17,221, depending on qualifications. Liberal fringe benefits. Non-discrimination in employment. Contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa 50308."

WANTED — Locum Tenens, Summer, 1967, June, July and August. Board eligible in internal medicine. University trained. Write: MINNESOTA MEDICINE — 374, 496 Lowry Medical Arts Building, St. Paul 55102.

Continuation Course

Continuation Medical Education Course in OB-GYN, April 27-28-29, University of Minnesota Hospitals. Speakers: Charles Hunter, M.D., OB-GYN Department, University of Washington and John Greene, M.D., Head of the OB-GYN Department of the University of Kentucky. Contact: William Albert Sullivan, M.D., University of Minnesota Hospitals.

Minneapolis Surgical Society

The Minneapolis Surgical Society will hold its 45th Anniversary Foundation Dinner, April 6, at the Minneapolis Club. Social hour and dinner will be at 6:00. Speaker will be John Cunningham Lilly, M.D., Communications Research Institute, Miami, Florida.

Minnesota Medicine at a Glance

Insulin Preparations — Kirtley

Page 315

A whole medical generation has grown up in which the emphasis in diabetic therapy has undergone a shift and the physician can — and indeed does — feel comfortable with this concept of oral therapy that was so startlingly new ten short years ago.

In the meantime, what has happened to insulin? The answer is that it still retains its place; in fact the growth in use of insulin continues, approximating fairly closely the annual increases observed before 1955. This indicates that each year more patients are found to require insulin in treatment. But if relatively little is being written as regards the clinical use of the sulfonylureas, even less appears concerning the routine management of diabetes with insulin. This dearth of published information can be held responsible, in part at least, for some of the surprises — not to say shocks — that some of us antediluvian specimens receive when discussing problem or even routine diabetic cases in a teaching situation with younger and obviously more eager colleagues.

Pregnancy with Complicating Diabetes Mellitus — Spellacy

Page 329

The author describes the maternal and fetal complications which occur during pregnancy associated with maternal diabetes mellitus. The management of the diabetic pregnant woman and the favorable effect on the incidence of complications by maintaining good diabetic control during pregnancy are pointed out. The problem of recognition of diabetes mellitus during pregnancy is also discussed. The importance of basing the diagnosis on an intravenous glucose tolerance test and the necessity of regulating the diabetes by the frequent measurement of blood sugar levels are emphasized. It is recommended that the infants of diabetic mothers be delivered between the 36th and 37th weeks of gestation, either by induced labor or caesarean section, in order to reduce the incidence of in-utero fetal death.

The Kidneys in Diabetes — Bloodworth

Page 335

This manuscript is a review of the current status of the understanding of the pathogenesis of vascular disease and diabetes as it occurs in the kidneys. The use of the electron microscope has made it possible to obtain more details than have been observed previously.

Tick Paralysis — Medical Seminar

Page 383

Though the wood tick in Minnesota has not been reported as causing disease, it is possible for the species to be a factor in paralysis caused by the neurotoxin which can be found in the salivary gland and in the egg of this insect. In that the wood tick makes its appearance in early spring, it would be well to review the clinical manifestations of this disease.

Pseudomembranous Enterocolitis — Grand Rounds

Page 405

Pseudomembranous enterocolitis is an occasionally encountered critical illness in which the etiology continues to remain obscure. The disease is so fulminating and the mortality so grave that it is well worth a review of the problems as reported in Grand Rounds.

BSP[®] DISPOSABLE UNIT

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

(50 mg. per ml.)

BROMSULPHALEIN[®]
IN A COMPLETE,
STERILE,
DISPOSABLE,
& ECONOMICAL
PATIENT-UNIT.

BSP, one of the more valuable single laboratory procedures for determining hepatic function, is now packaged in a complete individual patient-unit.

Each BSP Disposable Unit contains a sterile syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of terminally sterilized Bromsulphalein solution.

This all-inclusive disposable put-up lessens the chance of cross-infection and saves time and labor—the most costly commodities.

Diagnosis:

cystitis?
pyelonephritis?
pyelitis?
urethritis?
prostatitis?
in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.d.
(initial adult dose)

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function. Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately 25 mg. per pound of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of 500 mg. for adults, conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. 250 mg. for children, available in bottles of 56 and 1000.

References: (1) Based on 23 clinical papers, 1512 cases. Bibliography on request. (2) Bush, I. M., Orkin, L. A., and Winter, J. W., in Sylvester, J. C.: Antimicrobial Agents and Chemotherapy—1964, Ann Arbor, American Society for Microbiology, 1965, p. 722.

NegGram
Brand of
nalidixic acid
a specific anti-gram-negative

eradicates most urinary
tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.
- "Excellent" or "good" response reported in more than 2 out of 3 patients with either chronic or acute gram-negative infections.¹

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: E. coli, Klebsiella, Aerobacter, Proteus, Paracolon or Pseudomonas²... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Picture of low back pain

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100

President's Letter

THERE is developing an interest in a new medical school either in Rochester associated in some manner with the Mayo Graduate School of Medicine, or in St. Paul associated with the St. Paul Ramsey Hospital and the private hospitals in that city, or in Duluth.

The question of whether or not any new school, regardless of its location, shall be under the aegis of the University of Minnesota's Board of Regents is at issue. I know that tax money will probably be requested for both the building as well as the maintenance of such a new medical school. This would be in addition to the present support allocated to the University of Minnesota Medical School by the Legislature.

I believe that there is rather strong feeling on both sides of this question, and statements expressed here on this subject are strictly mine and do not represent the official opinion of the Council of the Minnesota State Medical Association.

Recently I spent some time talking with one of the officials of the American Medical Association Council on Medical Education. Some of the facts which I obtained from him are presented here:

Of the eighty-four schools listed in the 1965-1966 JAMA, Education Issue, 198:8:1066, ten are not associated with any university. Of the sixteen schools now being considered, only one is not so associated.

California, New York and Texas have multiple medical schools, all under a single board of regents. Inquiry indicated that there was intense competition among these schools, and in that official's opinion, each school was virtually autonomous.

There are at least four medical schools in the same community as their parent university but with separate campuses. About fifteen medical schools are located in different communities from the parent institution, separated by many miles. In one case, four hundred miles separates the two. All the remaining schools are on the same campus as the parent school.

It was this American Medical Association official's opinion that if a poll were to be taken of the medical school deans, the result would be a 90 to 95% vote in favor of university affiliation. He also felt that with such an affiliation it would be much easier to obtain an excellent faculty, especially in the basic sciences. It was his opinion that the faculties and students of the medical schools like to be in an atmosphere of academic excellence in related fields, such as mathematics, chemistry, physics and biology, which would be missing without such university affiliation. He also felt that the weakest schools in the country are those without such affiliation, particularly when measured in terms of faculty, graduate programs, research output and so forth.

I had started this discussion with the opinion that it would be much better to have no university connection. Obviously, I am no longer of that opinion.

Mystery of the Milksick

W. D. SNIVELY, JR., M.D.*
Evansville, Indiana

THERE ARE FEW diseases in the history of medicine that pose more puzzles than milk sickness. It is indeed "... a riddle wrapped in a mystery inside an enigma," to use Churchill's description of a quite different sort of puzzle.

But although this mystery has many facets, we can, as a result of our literature and field research, answer virtually all the questions associated with it. Here are the questions:

1. Why is milk sickness limited to the Midwest, Upper South, and Southwest?
2. Why did influential physicians on the Eastern Seaboard of the United States deny that the disease existed?
3. Why did the incidence of the disease decrease rapidly following the pioneer period?
4. Why were so few patients with milk sickness ever seen by city physicians?
5. Why do the cows whose milk causes the disease appear to be in perfect health after their calves and the humans who have drunk the milk have died?
6. How could one of this country's greatest physicians of the 19th Century, Dr. Daniel Drake, have failed to recognize the cause of the disease in spite of clear evidence?
7. Why did a world-recognized authority on bacteriology assert that the disease was caused by a bacillus in 1909?
8. How could a disease, perhaps the leading cause of death and disability in the Midwest and Upper South for over two centuries, go unrecognized by the medical profession at large until 1928?
9. How could a backwoods lady physician, inadequately trained and almost completely isolated from her fellow physicians, solve the mystery of the milksick and eradicate the

*Mead Johnson & Company, Evansville, Indiana; Clinical Professor, Department of Pediatrics, Medical College of Alabama.
Reprint requests to Dr. W. D. Snively, Jr., 2404 Pennsylvania St., Evansville, Indiana, 47721.

disease from her area almost a century before its cause was recognized by the American medical profession?

The Endemic

The milksick disease was first reported in the Midwest and Upper South in 1809. It had never been seen elsewhere — either in the United States, in Europe, or on any other continent. Certainly the pioneers along the Atlantic Seaboard knew nothing of it. If the Indians or their cattle suffered from the disease, they did not inform the early settlers. Not until the pioneers began to settle west of the mountains did the disease attract attention.

Apparently the first cases to be recognized occurred in the years shortly preceding the war of the Revolution. Then the ailment began to be seen more and more. In their opening chapter of the *History of Abraham Lincoln*, Nicolay and Hay said, "In the autumn of 1818, the new community of Pigeon Creek was almost exterminated by a frightful pestilence called the milk sickness, or in the dialect of the country, the milksick. It is a mysterious disease which has been the theme of endless wrangling among western physicians and the difficulty of ascertaining anything about it has been greatly increased by the local sensitiveness which forbids anyone to admit that any well-defined case has ever been seen in this neighborhood, although just over the creek or in the next town they have had it bad."

Because of the *milksick*, as the pioneers called it, numerous villages were abandoned. Evansville, Indiana, owes its prominent position in Indiana today, in part at least, to the fact that its early competitor, Darlington, was abandoned because of the milksick. Everything about the disease appeared mysterious except that many — perhaps most — of the persons afflicted with it died within five days to two weeks. Indeed, the mystery surrounding the ailment and its terrible fatality rate created a perfect panic among the early settlers. It was a terror that was spoken of only in whispers. Everyone denied that it had ever existed in his village or locality — up the river maybe; in the next val-

ley maybe; in a town over the ridge maybe, but *never here!* Read some quotations from early writers:

"Perhaps there is no disease [occurring with] such frequency and accompanied with such fatal results as milk sickness."

"Some of the fairest portions of the west in consequence of the prevalence of this loathsome disease must ever remain in an uninhabitable waste unless the cause and remedy can be discovered."

"Many of the finest portions of east Tennessee are known to produce this loathsome disease. Many of her most enterprising inhabitants have lost victims to it."

"No wonder pioneer families by whom malaria and typhoid were accepted as a matter of course fled back east in terror from this mysterious disease from which they died so suddenly. Their cattle and horses, apparently well, died after exercise and no one knew what it was."

"The Thomas family, our new neighbors, lost their tiny little children one September — victims to that most welcome of all childhood's nourishment — a draught of sweet milk."

"Another thing which impressed my youthful mind, although not strictly relevant to a medical article, was the hideousness of the nightly glare caused by the great fires built by the farmers to consume the bodies of their horses and cattle dead of the poison. I can never forget it."

"Horses frequently fall dead in the middle of the prairie leaving the traveler to make best of his way on foot. Cows have been known to expire in consequence of having been driven from the pasture to the barnyard."

"Danville, Indiana, has now become a perfect charnel house. No less than fifty died of milksick during the past year, and that too out of a population of 500 inhabitants."

"More than half the deaths that occurred in the early 19th Century in DuBois County, Indiana, were said to have been caused by milk sickness."

The Pharmacology

Milk sickness is really poisoning by milk from cows which have eaten white snakeroot (*Eupatorium urticaefolium*) or rayless goldenrod (*Haplopappus heterophyllus*). White snakeroot is found in the Midwest and Upper South; the rayless goldenrod, in the southwestern states, such as Arizona and New Mexico. White snakeroot is also called white sanicle, rich weed, squaw weed, snake weed, pool wort, and deer wort. It is a shade-loving plant frequently seen growing on roadsides, in damp, open areas of the woods, or on the shaded north side of ridges. The disease itself was variously designated as puking fever, sick stomach, the slows or sloes, stiff joint, swamp sickness, tires, trem-

bles* (especially as it affected animals), plus a long list of fanciful names. Poisoning by the rayless goldenrod is usually called alkali poisoning, since the rayless goldenrod grows only in extremely alkaline soils.

The Toxin

Perhaps the best designation of milk sickness is that of tremetol poisoning, since tremetol is an identified toxin that occurs in the white snakeroot and rayless goldenrod. Ether extraction of the leaves and stems of the white snakeroot produces tremetol, an unsaturated alcohol with the empirical formula $C_{16}H_{22}O_3$. In consistency and odor, tremetol resembles turpentine. The leaves of white snakeroot (don't eat too many!) have a menthol flavor; the blossoms give off a faint aroma as of lilacs.

Excretion of Toxin in Milk

Milk sickness can develop when man or animal eats the leaves or stems of the white snakeroot or rayless goldenrod, or drinks milk or eats butter from an animal that has eaten the plants. Perhaps it can occur when an animal eats heavily of the flesh or viscera of another animal that has died of severe white snakeroot poisoning. Milk secretors that ate white snakeroot were poisoned only late, since they excreted the poison into their milk.

While there is probably little white snake-root poisoning today, there may be more than health statistics indicate, since so few present-day physicians know about the disease. The correct diagnosis was made on two patients seen at the St. Louis Children's Hospital in 1963, only after they had been successfully treated for a strangely resistant acidosis. It probably would not have been made then had not the astute pediatric chief of staff remembered a patient with milk sickness whom he had seen some years before. Sporadic cases have been reported during the first half of this century. My yesterday's mail contained a letter from Dr. L. B. Newman, who wrote:

"I had a case in 1924 — white woman on small farm in east Tennessee. She had been sick 2 or 3 days when I saw her, and died 3 days later. Her most prominent symptom, as I remember,

was complete bowel paralysis, or obstipation, with resulting distention, which I was unable to relieve."

Case reports of cattle dying of trembles have reached us within the past two months. Although the disease appears infrequently in humans today, it was by no means infrequent in pioneer days. Even granting mistakes in diagnosis, the ailment might well have been the leading cause of death and disability in many Midwest and Upper South communities during the 18th and 19th Centuries. It was epidemic in dry years when cows wandered from their brown pastures into the woods in search of forage. As more forests were cleared so that cattle had adequate pasturage, even in dry weather, and as fences were built to keep the cattle in the pastures, the incidence of the disease tapered off.

It was persons who had drunk heavily of the raw milk of a severely poisoned cow who developed milk sickness. These were usually the milk lovers. When they became ill and took to their beds, appetite-depressed, energy gone, what was the food on which they chiefly subsisted? Tragically, milk! In fact, some physicians used charcoal suspended in milk as therapy. Mixing milk of several cows diluted the poison so that the toxic level was not reached. It was for this reason that little milk sickness was seen in population centers; for this reason also, city doctors almost never saw milk sickness.

Organs Affected

The severity of milk sickness relates directly to the dose of tremetol ingested. Its effects are both intense and widespread, severely affecting the liver, brain, kidneys, heart, and mucosa of the stomach and intestines. But the aspect of the disease that places the patient in the direst peril is the vicious acidosis it causes. Unless vigorously treated, this increased hydrogen ion concentration of the body fluid kills within a maximal period of two weeks. It was all that Hartmann and his group — experts in the field of acid-base disturbances with the best of modern-day facilities — could do to correct the acidosis in their two patients suffering from the ailment. The physician to-

*See Test Your Word Score Page 521.

day can but view with awe the plight in which the pioneer doctor found himself when confronted with a patient suffering from acute milk sickness.

Symptoms

In Animals

When milk sickness occurs in animals, chiefly cattle, it is called trembles. The animals suffer from anorexia, weakness, falling, stiffness, and *trembling*; hence the name. Abdominal distention and unconsciousness occur.

In Man

In man the symptoms include anorexia, listlessness, weakness, vague pains, muscle stiffness, vomiting, abdominal discomfort, severe constipation and, most important of all and underlying most of the other symptoms, profound acidosis. Because of the acidosis, the breath smells of acetone, described in days gone by as an overpowering "feter." In both man and animal, death often comes quickly. The disease can become chronic or latent; it is prone to recur if the individual is subjected to fatigue, starvation, intercurrent infection, or vigorous exercise.

The lethargy that characterizes the patient who has never completely recovered from his attack of milk sickness helped give it the name of the slows (or sloes). When Blair protested the removal of McClellan from his command, Lincoln said, "I said I would remove him if he let Lee's army get away from him, and I must do so. He has got the 'slows,' Mr. Blair."

Treatment

The modern-day physician would be correct in treating milk sickness if he attacked the acidosis vigorously. Dr. W. E. Walsh employed sodium bicarbonate in 1908, summarizing his findings in a splendid article in the *Journal of the American Medical Association* in 1926. Whether ethyl alcohol, either as such or in the form of brandy, helped cure milk sickness by neutralizing tremetol can be questioned, although several physicians endorsed beverage alcohol as a sure remedy.

The Medical Record

According to the medical literature, milk sickness probably occurred in North Carolina as early as the American Revolution, where a mountain peak today is called Milk-sick.* The Indians probably knew snakeroot poisoning as a disease of cattle, although the first published account was that of Thomas Barbee, who described it in 1809. But not until 1811 did the disease have a published name — sick stomach. The anonymous author of the 1811 article knew as much about the disorder as did most writers for a half century to come.

During the fearsome epidemic of 1818, milk sickness claimed Nancy Hanks Lincoln, mother of Abraham Lincoln; Nancy's great aunt and great uncle; and a neighbor — all at Pigeon Creek in Indiana. In searching for evidence of white snakeroot around the Lincoln cabin site at Pigeon Creek, we found one of the most dense stands we have ever seen — within a hundred yards of the cabin.

Early Research

In 1841 two erudite but unscientific publications appeared. In one of these, Dr. Daniel Drake, who had never examined a patient with the ailment, wrote at enormous length on it. He discounted the evidence produced by John Rowe, a farmer of Fayette County, Ohio, who in 1838 informed the local newspaper that he had discovered that white snakeroot was the cause of trembles in cattle. He had killed a calf and two cattle by feeding them the plant, a pig by giving it a fluid extract from crushed leaves and stems. With arrogance seldom surpassed in medical history, the great Professor Drake wrote: "A professional scrutiny only can be relied on in such cases. The testimony adduced by Mr. Rowe is, therefore, defective and inconclusive." Drake then mentioned his pet — and far from conclusive — theory, namely, that poison ivy caused the disease.

Theories of Etiology

In the years that followed, the number of theories as to the cause of milk sickness was almost as great as the number of writers.

*In the Snowbird Range, near Robbinsville, N. C.

One said the cause was arsenic; another asserted it was mysterious soil organisms; another attributed it to mysterious exhalations from the ground, and so on. Finally, in 1928, Couch reported isolation of three poisonous substances from the white snakeroot — a volatile oil and a resin acid that do not produce trembles, and an oily liquid with the characteristics of a secondary alcohol that does. The last he named *tremetol*. Since 1928, there have been nine articles published in the chemical literature on the precise chemical nature of tremetol. Thus, at long last, did the scientific community recognize in specific terms the cause of the ailment.

The importance and seriousness of the acidosis that accompanies milk sickness was recognized clinically by Walsh in 1909 and documented both with clinical observations and with blood chemical findings by Hartmann and his co-workers at Washington University in St. Louis in 1963.

A host of peculiar facts strikes one as he reads the written chronicles of milk sickness: First of all, few writers observed the highly important and characteristic fetor of the breath, which gives one the clue to acidosis, probably because so few had examined patients with milk sickness. Many authors have assumed the ailment affected the organs from which symptoms originated. Thus anorexia and vomiting, really caused by the acidosis, gave the disease the names puking fever and sick stomach. In the case of most authors, their opinions concerning the cause of milk sickness were strongly influenced by the medical fashions of the times. In addition, many authors approached the study of the disease with their minds made up as to what caused it. Fortunately, there was an exception to these general statements: a remarkable woman by the name of Dr. Anna Pierce Hobbs Bixby.

The Doctor Anna Story

Little Anna Pierce was a blue-eyed sixteen-year-old when she rode west from Philadelphia with her family in an ox-drawn covered wagon. Following the Wilderness Road, the Pierce family drove down into Kentucky, crossed the Ohio River at James Ford's

"Ferry Ohio" in 1824. But the Ford's Ferry gang coveted the blooded horses, fine cattle and nest egg of gold coins with which the Pierces hoped to buy a farm in the western country. They pursued the Pierces, who turned off the main trail into the hill country, thus escaping the robbers in a thrilling sequence of events that the old settlers in Little Egypt (Southern Illinois) still talk of around the pot-bellied stoves and fireplaces in their hilly wilderness during the winter months.

The Pierces created a farm from that wilderness not far from what later became Rock Creek Settlement in southeastern Illinois. The same farm is owned today by Clifford Joyner, who points to the site where the imposing two-story Pierce log house once stood. Anna, a conscientious youngster, was immensely disturbed by the health problems experienced by the pioneers. Determined to become a physician, she traveled to Philadelphia, where she took all the professional courses that a woman could take — courses in nursing, midwifery, and tooth-pulling. She returned to Rock Creek about 1828 to become the only physician of the community for many years.

As A Health Practitioner

As the only health practitioner in southeastern Illinois, Dr. Anna — in later years affectionately called Granny Bixby — was able to cope fairly well with the frontier ailments until an epidemic of a strange and fearsome disease ravaged the settlement. Dr. Anna quickly observed that the men and animals who were contracting the disease had invariably been drinking milk. She was deeply concerned with the ailment, which was highly fatal, and the course of which her treatment failed to influence. Her concern became even more acute when the disease killed her mother and her sister-in-law, Mary Hobbs, as well as making her father seriously ill. Anna determined to find the cause of the disease. After noticing its association with milk, she observed that the ailment was seasonal, beginning in June and ceasing after the first frost. Then she saw that although men and animals were dying of the

disease, milk cows appeared not to be affected until after those who had drunk their milk had sickened and died.

In her diary, Anna wrote, "I am convinced now that the poison which kills the calves and people saves the cows by being daily discharged through the milk glands. So, I am writing a few letters this morning and tell-

Fig. 1 — Entrance to Bixby Cave, where Eson planned to keep Anna captive.

Fig. 2 — Map showing states in which milk sickness was reported in the scientific literature during the 19th Century.

ing everyone I can to abstain wholly from milk and butter from June until after killing frosts." Then Anna saw that few horses, sheep and goats developed milk sickness. She concluded that an herb was causing the disease, reasoning thus: "Sheep and goats are careful in selecting their foods, and horses are what teachers call graminivorous; that is, grass eaters, while cattle are herbivorous and not careful in selecting. These things prove to us that it is not a grass but an herb that is spreading sorrow and death among us."

An Astute Observer

Convinced that the culprit was an herb, Anna began a systematic search of the woods. Day after day she followed the cattle, examining the plants that they ate. Then one day in the fall of 1834 her searches were richly rewarded. Early that morning, Dr. Anna had hiked into the densely forested Hobbs Ridge, carrying an herb basket, a frugal lunch, with rifle and dogs for protection. She followed the cattle, as she had so many other times, picking specimens of the herbs on which they fed. About noon, she spied an Indian squaw cowering in the underbrush. When Anna called to her to come out of hiding, the old squaw did so. Anna gave her her lunch and was delighted to find that the old woman was an Indian medicine woman fleeing from the forced migration of Shawnee Indians over the Ohio River that occurred as a result of the Treaty of 1833.

Anna took the squaw into her home, where she remained until her death many years later. The old woman soon learned of Anna's interest in the disease of milk sickness and led her to the north slope of Hobbs Ridge, where she showed Anna the white snakeroot plants that caused trembles and milk sickness. Anna gathered a basketful of the weed and showed it to her husband, Jefferson Hobbs. Jefferson, being of a practical (and skeptical) turn of mind, fed several bunches of the plant to a calf, which developed typical trembles. Now Anna was convinced that she had found the cause of the milk sickness.

Method of Eradication

Anna began a systematic program to uproot and burn all the white snakeroot in southeastern Illinois. Under her guidance, men and boys of the pioneer community carried out the program for three years, at the end of which the weed and the disease were said to have been eliminated from the area. Now white snakeroot is again extremely prevalent in southeastern Illinois, as it has always been throughout the Midwest and Upper South.

In order that doctors in other pioneer communities might learn to recognize white snakeroot, Anna raised a small crop of it in her garden. She wrote letters inviting physicians to come and examine the plant.

The second winter after Anna had shown that white snakeroot caused milk sickness, her husband died of a virulent, epidemic form of pneumonia. Overwhelmed by his death, Anna still managed to carry on her work as the only doctor in the area. She did more: she founded the Rock Creek Church, which still stands. Some years later she married a young ne'er-do-well, Eson Bixby, apparently intending to reform him. Her attempts were wretchedly unsuccessful, and Anna and her husband were separated. Later he returned and, disguised, kidnapped Anna one night, taking her to one of the seven caves of Hooven Hollow, even today one of the wildest and most primitive areas of the entire Midwest. In an effort to escape from her heartless captor, Anna leapt from the top of a cliff. Her ankle broken or sprained, she still managed to crawl into the underbrush and elude Eson. Apparently she never entirely recovered from the terrible experience. Still she continued to serve the Rock Creek Settlement as its only physician. When she died in 1869, she had received no recognition for her remarkable discovery of the cause of the milk-sick.

Delay on Identifying the Cause

Milk sickness occurred sporadically. This made it extremely difficult to make sequential observations. Next, it appeared probable that various species of white snakeroot, al-

though similar in appearance, vary greatly in toxicity. For example, careful analysis according to accepted techniques in the Mead Johnson Research Center Control Laboratory has failed to reveal tremetol in specimens of white snakeroot gathered locally.

Fig. 3 — View of the "Anna Country" from the hills to the north.

Fig. 4 — Now abandoned road over which Dr. Anna rode on horseback on her errands of mercy.

Fig. 5 — Dr. Anna and her niece, Elizabeth Ann Hobbs Foster. When Elizabeth Ann was five weeks old, Dr. Anna carried her on horseback from St. Louis, Missouri, to Rock Creek, Illinois, a distance of over 130 miles.

Third, milk secretors, such as cows, escaped poisoning early by excreting the tremetol into their milk.

Fashionable medical belief in miasmas and exhalations from the ground as causes of disease led many physicians to think that these factors caused the milksick. The disease superficially resembled arsenic poisoning, which misled others. Non-professional people, excellent observers like John Rowe, were held in disdain, while physicians like Dr. Daniel Drake, though rigid, opinionated and unobjective, were held in awe.

As the white snakeroot was sometimes infected with a bacillus and this same bacillus was found in patients dying from milk sickness, it was difficult for the physicians to believe that the bacillus was a completely innocuous plant bacillus. Indeed, in his textbook of bacteriology a famous authority attributed the disease to a bacillus.

There was a woeful lack of medical communication. Medical journals, medical societies and medical meetings as we know them today did not exist in the backwoods areas. Even in the populous centers they were in a primitive state of development. Hospitals, where physicians could meet and exchange ideas, were nonexistent until nearly the middle of the 19th Century. Because white snakeroot, hence milk sickness, was limited to the Midwest, Upper South and Southwest, influential eastern physicians refused to believe it existed.

These factors contributed to the greatest of all mysteries associated with the milksick: why it took the medical profession so long to discover the cause of the disease. In view of the complexity of the mystery, we should not be too surprised that some of the most distinguished physicians of the 19th Century, and even of the early 20th Century, failed to solve the enigma. But we certainly can be amazed that these same sources of confusion failed to keep Dr. Anna from walking down the path of accurate observation and logical reasoning that led her to the cause of the terrible plague.

Summary

In discussing Dr. Anna's remarkable discovery with my co-researcher, Louanna Furbee, I expressed the opinion that Dr. Anna made her remarkable discovery of the cause of the milksick *in spite of* her isolation and her lack of a real medical education. Miss Furbee disagreed. She felt it was *because of* Dr. Anna's isolation and lack of education. Because of her isolation, Miss Furbee pointed out, Dr. Anna had learned to depend on herself and had not developed a slavish respect for the opinions of older authoritarian colleagues. Further, because she had not been perfused with the medical theories of the time, she was able to view the ailment with objectivity.

But whether it was *in spite of* or *because of*, no one could question that Dr. Anna was a keen observer. Some persons observe specifics but neglect to see generalities. Others can see general concepts but fail to perceive individual cases. Dr. Anna was one of those rare persons who could do both. She could see the woods *and* the trees:

... She discovered that the white snake-root caused milk sickness.

... She reproduced the disease in a calf four years before farmer John Rowe did.

... She carried out the first, and perhaps the only, white snakeroot eradication program.

... She recognized the cause of the disease nearly a century before it was recognized by the medical profession as a whole.

Clearly, she was a woman of rare talents, unusual dedication, remarkable perceptivity. She richly deserved the title that was given her by her biographer, Elihu Hall, "Angel of the Ozarks."

Acknowledgments

The research project that led to the verification of Dr. Anna's role in the discovery of the cause of milksick involved many persons, who gave unstintingly of their time and knowledge. Among these were Louanna Furbee; Thomas S. Acker, SJ, Ph.D.; John W. Allen; Arthur N. Bahn, Ph.D.; Colonel George Morgan Chinn, Director, Kentucky State Historical Society; L. A. Dearinger; Ivy K. Joyner; Betty Lou Keenan; Walter Page; J. D. Quarant; and Gertrude Tyer.

Amebic Liver Abscess

HARRISON H. FARLEY, M.D.
JOHN H. LINNER, M.D.
Minneapolis, Minnesota

THE PRESENCE of hepatic abscesses in fatal cases of dysentery had been noted for many years, but it was not until 1887, when Kartulis in Egypt found amebae in an hepatic abscess of a patient with amebic dysentery, that the cause-effect relationship was established.²

Many have undoubtedly died from this complication of amebiasis without the diagnosis being suspected. In fact, it would appear that hepatic amebic abscess may very well have been the cause of the death of Napoleon the Great, with his gastric ulcer only an associated finding.³ The big step forward in the treatment of this worldwide disease was the discovery of the efficacy of emetine in the treatment of hepatic amebiasis by Rogers in 1912.²

Incidence

The incidence of amebiasis is, in several dozen surveys in the United States, found to be from 3-20%.² It may occur in epidemic form, as it did in the notorious outbreak in Chicago in 1933, or in sporadic case form.

Amebiasis occurs in Minnesota but is not common; however, it should be suspected in anyone who has had a gastrointestinal upset subsequent to a visit to an endemic area. Statistics differ as to the number of patients who have amebic dysentery and then develop an amebic abscess, depending upon whether it is an autopsy series or a clinical series; but 36% in the former and 11% in the latter are fairly average figures.⁴ The three cases to be presented all occurred in persons who arrived in Minnesota immediately following a stay in a foreign country. They were therefore considered prime candidates for amebiasis from the start.

Pathogenesis²

The protozoan *Entamoeba histolytica* is transmitted via the anal-oral route. There are six species of ameba parasitic in man,

but only *E. histolytica* is pathogenic. The encysted forms that survive external exposure and are ingested have walls that resist the action of the acid in the stomach but break down in the alkaline media of the small intestine, where the trophozoites emerge and penetrate the bowel wall, then gain access to the tributaries of the portal vein and are transmitted to the liver. On reaching the liver they lodge in the sinusoids, and a vigorous local reaction results — the stage of amebic hepatitis. If the amebae are not destroyed they cause necrosis

and small abscesses which coalesce to form larger single or multiple abscesses. A considerably larger number develop hepatic amebiasis than develop abscesses; apparently there is a distinct amebastatic ability of the liver to keep them in check until appropriate therapy is instituted.²

Clinical Course

The patient with a liver abscess may have it concurrent with the intestinal phase or months later. The signs and symptoms vary with the size and position of the abscess and the presence of other complicating features of the disease. Weight loss, intermittent fever, and abdominal discomfort are commonly present. Hepatomegaly may be present but jaundice is frequently absent. The presence of more than one abscess is ominous; DeBaKey and Ochsner found that in their large series of amebic hepatic abscess or hepatitis there were no known survivors of multiple abscesses.⁴ In another study of 148 fatal cases of amebiasis, 61% had hepatic abscesses.⁷ However, in this same study liver abscess as a significant cause of death was third in order, preceded by intestinal perforation and unchecked dysentery.⁷

Case Histories

Case 1

A 43-year-old man was admitted to Swedish Hospital on 8-23-65 from Lagos, Nigeria, where he had lived for the past nine months while working for an airline. Six to seven weeks prior to admission he had become ill with chills, fever, and jaundice. Hepatitis was suspected, and he was treated with antibiotics and rest with some improvement, though his general condition began to deteriorate. An x-ray of the stomach revealed a duodenal ulcer. A lesser sac abscess was suspected, and he was transferred to the United States for definitive treatment.

During his stay in the tropics he had gradually lost 28 pounds, but he attributed the loss to his difficulty in adjusting to the diet. He did not complain of diarrhea and, other than an initial spell of vomiting following a sea-food meal, he had had no gastrointestinal complaints.

Physical Findings

Physical examination revealed an acutely and chronically ill man with a large mass that was felt to be contiguous with the liver, occupying the right upper quadrant and epigastrium. He was febrile and had a gray jaundiced color. His pertinent laboratory work is seen in Table 1.

A barium enema and an oral cholecystogram were normal, but an upper gastrointestinal series re-

Fig. 1 — Diagnostic liver scan showing large left lobe space-occupying lesion.

Fig. 2 — Operative Skiodan study of cyst.

vealed an active duodenal ulcer crater, and the stomach was displaced to the left and anteriorly by a mass. Although a lesser sac abscess was a definite possibility and in spite of the fact that several stools were negative for ova and parasites, a neoplastic process or cyst in the liver was thought to be a possibility. An Au¹⁹⁸ liver scan (Figure 1) was performed, revealing the right lobe to be normal but a large space-occupying lesion to be present in the left lobe.

TABLE 1

	Case 1	Case 2	Case 3
Sedimentation rate	103	80	122
WBC	14,600	16,700	16,300
Hemoglobin	11.2	13.4	11.1
Bilirubin	0.6/2.4	0.4/0.9	0.4/1.1
Ceph floc	3+	—	3+
Alk P'tase	39	19.2	7.8
A/G ratio	2.8/3.7	3.3/3.3	2.4/3.6
Pro time	11.4/14.0	—	14.0/15.0
Bromsulphalein	—	30%	12%
T.T.	—	1	—

Surgical Management

At surgery the left lobe of the liver was remarkably enlarged and slightly darker in color, but its capsule appeared normal. Needle aspiration deep into the left lobe revealed a slightly hemorrhagic, grayish purulent matter to be present. Repeated aspirations with a #13 needle resulted in the removal of 1300 cc. of pus. Injection of Skiodan into the cavity (Figure 2) revealed it to correspond to the left lobe space-occupying lesion as seen on the preoperative liver scan. A #20 Foley catheter was placed in the cavity, brought out through a stab wound, and subsequently connected to straight drainage.

All laboratory studies on the aspirate revealed

only a para colon bacillus on sub culture. No biopsy of the abscess wall was obtained — nor was it feasible to obtain scrapings. However, serum sent to the State lab showed a *positive* hemagglutination test for amebiasis. Postoperatively the patient was treated with emetine 65 mgm. daily × 5 and chloroquine 250 mgm. q.i.d. × 21 days. He was also treated medically for his duodenal ulcer. His recovery was rapid and he was discharged on 9-9-65. Six months later he wrote from Nigeria stating he felt well and had regained his lost weight.

Case 2*

A 55-year-old male was admitted to Swedish Hospital on 3-30-66 because of fever and chills for five days prior to admission. He had been started on tetracycline and penicillin, which had not affected his temperature.

His symptoms had begun about one week after his return from a vacation in Mexico. During his stay there he had suffered at times from bouts of mild gastroenteritis. On admission he was having frequent and loose blood-tinged stools. However, on repeated examination of his stools neither trophozoites nor cysts were seen.

Physical Findings

Physical examination revealed a mild tenderness to palpation in the right upper quadrant.

It was suspected that the patient might have a liver abscess in spite of the negative stool findings, and a liver scan with Au¹⁹⁸ was ordered. This revealed two definite areas of decreased pick up, one in the right lobe and one in the left lobe.^{xx} (Fig. 3) Liver abscesses or metastatic tumor in the liver were suspected.

Surgical Management

He was started on emetine, chloroquine, and Duquaine therapy on 4-3-66, and on 4-11-66 his abdomen was explored through a right subcostal incision. The liver was characterized as having a darker than

Fig. 3 — Preoperative Au¹⁹⁸ liver scan showing multiple space-occupying lesions.

normal color. Aspiration with a #13 needle in several places where bulging was noted revealed three distinct cavities containing 70, 40, and 60 cc. of "anchovy paste" pus. Two abscesses were in the right lobe and one was in the left. Penrose drains were placed close to the puncture sites and one cavity was curetted.

No cysts, trophozoites, or bacteria were found in the scrapings, but the course of anti-amebic medical therapy was completed. He made an uneventful recovery and was discharged on 4-26-66. The clinical history, type of material found, and rapid response to anti-amebic therapy make the diagnosis of amebic liver abscess quite likely.

Case 3

A 40-year-old female missionary returned to the United States after 3½ years of service in Mexico. Six days before admission to Swedish Hospital she developed mild indigestion, anorexia and right upper quadrant pain. When her symptoms persisted she was admitted on 8-28-62.

Physical Findings

No jaundice was present, but there was tenderness to palpation in the right upper quadrant, although no mass was felt. She had had amebic dysentery earlier during her stay in Mexico, but this was successfully treated. The initial diagnosis after all studies had been completed was cholecystitis; but amebic liver abscess was considered a likely possibility.

A proctoscopic examination was unremarkable, but trophozoites of *Entamoeba histolytica* were seen on examination of a stool specimen. On 8-30-62 she was started on emetine and chloroquine therapy.

Surgical Management

At surgery on 9-1-62 a right subcostal incision was utilized to explore the right upper quadrant. The gall bladder was normal, but the dome of the right lobe of the liver was adherent to the diaphragm. Blunt dissection in this area revealed a 4 × 5 cm. cavity containing pus. After evacuation of the purulent matter a mushroom catheter was placed in the cavity and brought out through a stab wound.

There was no growth on culture of the material. A course of emetine and chloroquine was completed following surgery and all stools became negative for trophozoites or cysts. She was discharged from the hospital and has been followed for four years with no recurrence of her symptoms.

Discussion

Amebiasis should have been suspected preoperatively in Case 1 simply because the patient came from the tropics. Neither trophozoites or cysts were found in Cases 1 and 2, but this should have been followed up by proctoscopic examinations. Even though diarrhea may not be present, small ulcerations may be seen, and scrapings from these areas frequently reveal the ameba when the stool

does not.⁶ Usually cysts are discovered in formed stools, whereas trophozoites are seen in watery stools.⁶

Eosinophilia is not commonly present, although it was observed on one differential in Case 2. The wbc. is usually elevated along with the sedimentation rate. This was true in all three cases presented. It seems that the clinical deterioration is correlated with the amount of pus present in the liver. The patient (Case 1) who had a cyst containing 1300 cc. was extremely ill. The presence of jaundice is variable and not particularly helpful in making the diagnosis. Although liver cellular tests may be abnormal, they are of little help in deciding whether an abscess is present as opposed to amebic hepatitis.

Liver-scan studies utilizing Au¹⁹⁸ or Rose Bengal¹³¹ as originally described by Friedell⁵ are of great assistance in determining whether an abscess of significant size is present in the liver. Scans were done on two of our patients and were helpful in localizing the abscess. If there is a single abscess close to the surface of the liver it may be aspirated percutaneously. If open aspiration is to be done the choice of incisions is aided. Serial scanning of the patient in his convalescent course may be done to determine resolution of the abscess cavity. An Au¹⁹⁸ liver scan subjects the liver to approximately 0.5 to 3.5 r. irradiation; this is in contrast to 9 r. on a cholografin examination of the gall bladder.¹

Closed vs. Open Aspiration

The advantages of open over closed aspiration are illustrated in the three cases presented. Closed aspiration of Case 3 would have had to be through the pleural cavity and would have risked contamination of this space. In Case 2 there were three distinct abscesses. It seems unlikely that they could have been localized as well and drained as completely through the percutaneous route as through an open incision. The position of the abscess deep in the left lobe in Case 3 makes difficult a successful percutaneous aspiration. It should be said, however, that closed percutaneous aspiration is superior to open aspiration if the abscess cavity can be

accurately localized close to the surface of the liver.¹

Medical Treatment

It does not seem unreasonable to assume that considerable pus may remain after aspiration. This certainly seems likely in Cases 1 and 2. Yet the patients made prompt and complete recoveries. This we must attribute to the efficacy of emetine and adjuvant anti-amebic therapy. Many cases of hepatic amebiasis with micro-abscesses are undoubtedly cured by these efficacious drugs before reaching the large abscess stage.⁴ It should be emphasized that emetine therapy is not without its hazards, and close clinical scrutiny must be maintained during treatment.

Finally it should be added that amebic hepatic abscess is only one of many serious complications that can follow amebic dysentery. Ulceration and perforation of the colon with peritonitis, stricture formation with obstruction, appendicitis, rectal ulceration and fistula formation, and other extra-intestinal areas of involvement (i.e., lung) can all occur and may be more devastating.²

Summary

Amebiasis is notorious for its wide-spread distribution. Amebic hepatic abscess is one of several complications that may occur following amebic dysentery. Three cases of amebic hepatic abscess were successfully treated by open surgical drainage and anti-amebic medical therapy.

Green Medicinals

Herbs for the Reproductive Organs

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them. To benefit the reproductive organs herbalism proffers arbor vitae, burdock, eryngo, groundsel, marjoram, pennyroyal, tansy, and wild thyme.

Besides being wholesome, tansy fritters sound appetizing:

Tansy Fritters

Take the crumbs of a small loaf of bread, pour on it half a pint of boiling milk; let it stand an hour, then put in as much juice of tansy as will give it a flavour, but not to make it bitter, then make it a pretty green with spinach juice, put to it a spoonful of ratafia* water, or brandy. Sweeten it to taste, grate over it the rind of half a lemon, beat the yolks of four eggs, mix them all together, put them in a tossing-pan, with four ounces of butter, stir it over a slow fire till it is thick, take it off and let it stand two or three hours, then cut into fritters and drop them into a pan of boiling lard; a spoonful is enough for a fritter. Serve them up surrounded by slices of orange, grate sugar over them, and serve a wine sauce separately. — Elizabeth Raffald (1825)

*See Test Your Word Score Page 521.

From Hufeland's Makrobiotik*

On the 2nd of August, 1790, a carabinier named Petit jumped into the river from one of the windows of the Military Hospital at Strassburg. Half an hour later, — as nearly as could be learned from an inquiry that was made at the time of the occurrence, — his body was taken from the water and carried into the hospital. To all appearances the man was dead; no evidences of life were discovered. Nevertheless, efforts were made to revive him. The body was placed in a thoroughly warmed bed, with the head lying high up on a pillow, the arms resting on the trunk, and the legs extended side by side. The only other measures adopted were the following: At short but regular intervals of time heated cloths were placed over the region of the stomach and over the legs; and heated stones wrapped in cloths were placed in different parts of the bed. At the end of seven or eight minutes a slight twitching of the man's upper eyelids was observed, and a short time afterward his lower jaw, which up to that moment had been in firm contact with the upper jaw, became separated from it and permitted a little frothy mucus to escape between the lips. After this discovery had been made, a little wine was cautiously introduced into the man's mouth. Apparently it was swallowed, and then other small doses of wine were administered, all of them apparently being swallowed. Under this stimulation the pulse beats at the wrist became perceptible, and at the end of one hour the man was able to answer questions.

— Christoph Hufeland (1762-1836)

Buckle Up

Highway Hypnosis

Among the most frequent causes of accidents on freeways is highway hypnosis — the purr of your engine; the hum of your tires; the white ribbon of highway unfolding endlessly ahead; the hypnotic sameness which lulls you into a trance.

You gain a false sense of security. You're not aware of traffic conditions around you. In a sub-alert state you may doze at the wheel or drive off the road. You lose your ability to judge speed and distance.

You can combat highway hypnosis by:

Stopping often to freshen up and check your car. Frequent stops not only enable the motorist to refresh himself, but allow time for dissipation of heat built up by tires during continuous high-speed driving. While you are stopped, wash up — have a bite to eat — walk around — take a nap — get gasoline — have some coffee — NOTHING STRONGER!

You can also help yourself to stay awake by checking your speedometer often — keeping a window open for fresh air — avoiding a fixed eye position by keeping the eyes moving — listening to lively radio programs — chewing gum — singing and talking aloud — cracking a smile to ease the strain — changing drivers often — eating lightly — keeping your mind active by concentrating ahead — and being interested in what's going on outside your car.

A New Intra-Articular Steroid

**with
Prolonged
Anti-
Inflammatory
Action**

PAUL J. BILKA, M.D.*
Minneapolis, Minnesota

THE INTRA-ARTICULAR use of adrenocorticosteroids is an established and valuable therapeutic tool in the management of many rheumatic disorders.¹ In rheumatoid arthritis it is useful as an adjunct in the patient whose active synovitis is limited to or is especially severe in one or a few joints. If hydrocortisone acetate is injected into an active rheumatoid joint, marked reduction or complete relief of local inflammation can be expected to occur within 24 hours and to last for an average of one to two weeks. If a more insoluble ester of hydrocortisone is injected, namely hydrocortisone t-butyl acetate, similarly rapid improvement can be expected, but the duration of effect is lengthened two or three-fold to an average of four weeks.² Various modifications of multiple steroid analogs** have failed, to the present time, to materially improve upon the effectiveness of hydrocortisone t-butyl acetate. An exception is the brief report by Hollander et al. in 1961.³ The purpose of this report is to present data on a new steroid that has a significantly prolonged local anti-inflammatory effect in patients with rheumatoid arthritis.

Present Study

One hundred and twenty-five patients with active rheumatoid arthritis were selected as test subjects for the new steroid. All patients met the American Rheumatism Association criteria for the diagnosis of either definite or classical rheumatoid arthritis. All injected joints had objective clinical evidence of swelling as demonstrated by free fluid or synovial thickening and all demonstrated synovial tenderness. Joints with inactive disease, or with largely destructive or me-

chanical changes were not included in this study.

The drug used is triamcinalone hexacetonide, which differs from the parent compound triamcinalone by possessing an acetonide group at C-16 and C-17 and a tertiary butylacetate radical at C-21 instead of free hydroxyl groups at these carbon atoms. This modification makes the compound much less water-soluble, thereby prolonging its duration of action. The drug was provided as a fine crystalline suspension containing 20 mg. of triamcinalone hexacetonide per cc. of solution.* Unless otherwise stated, one cc. of the suspension was injected into each joint.

Degree of Relief

The 125 patients were given 289 separate injections of triamcinalone hexacetonide as detailed in Table 1. The initial post-injection examination was usually made at one week, with subsequent examinations at one to four-week intervals. Joint swelling and tenderness were recorded on a grade zero to four basis, and range of motion was recorded in degrees. A statement from the patient of an estimate of the local joint improvement was recorded, and was usually supportable by "objective" criteria such as ability to walk without a limp, ability to turn a faucet or door knob with one hand, etc. In the case of the one patient who had two hip-joint injections, the assessment of improvement was based on her subjective estimate, plus range of hip motion, inasmuch as palpation of the hip synovium is rarely possible.

Following 267 injections, or in 92.3%, the patient obtained over 90% local symptomatic relief plus objective reduction in joint swelling and tenderness. In seven injections, or in 2.4%, the result was listed as poor — or less than 25% relief. Four of these seven poor results followed ankle injections. Two injections (0.8%) were classified as "good," with 50% to 90% relief, and 13 injections (4.5%) were classified as "fair" with 25% to 50% relief. These results are not too different from those reported by other authors using several other types of intra-articular steroids.

*Supplied by Lederle Laboratories, Pearl River, New York.

Duration of Relief

This was the next significant feature studied and the details are presented in Table 2. Only the 267 injections with an initial "excellent" response are here analysed. When an injected joint begins to lose its local anti-inflammatory effect, it returns to its pre-injection state rather rapidly, usually within one week. In this assessment, as soon as a joint went below 90% improvement it

TABLE 1

Triamcinalone hexacetonide and hydrocortisone TBA equal duration	15	32
Triamcinalone hexacetonide longer duration than hydrocortisone TBA	58	92

was recorded as at the termination of its "excellent" response. It is seen that in over half of the injections the full benefit lasted for longer than three months, and in only 6% did the "excellent" response last for less than one month. It may be of interest that the non-weight bearing joints appear to have a greater percentage of long lasting results. This could reflect the effect of trauma in causing an earlier return of inflammatory signs to a weight bearing joint.

Reactions

There were seven instances, in seven patients, of increased local pain or inflammation following the injection with triamcinalone hexacetonide. Three of these followed finger injections where the volume of material (0.5 cc. in two instances and 1 cc. in another) injected into a small joint could have played a traumatic role. Two reactions followed ankle injections, and one each followed a wrist and an elbow injection. Three of the reactions were relatively mild, and all seven post-injection flares subsided within four days following only symptomatic therapy. Five of these patients had other joints injected with triamcinalone hexacetonide without local reactions. The cause of these transient flares is uncertain, but very likely the trauma of the injection is a factor. McCarty and Hogan have also suggested the role of a foreign body type reaction to corticosteroid crystals.⁴

Systemic Effects

It is not uncommon, following an intra-articular injection of hydrocortisone acetate, or especially one of its more potent soluble analogs, for patients to experience a generalized subjective or objective improvement of mild to moderate degree lasting for as long as several days. This is believed to be due to systemic absorption of the drug, but how much is due to psychogenic influences is uncertain. With the use of hydrocortisone t-butyl acetate these systemic responses are minimized. Although each cc. of triamcinalone hexacetonide contains 20 mg. of a potent adrenocorticoid which is the equivalent of 100 mg. hydrocortisone, it is postulated by the manufacturers that the insolubility of

the compound is unlikely to cause significant systemic effects from absorption at the injection site. Nevertheless, 26 patients on 35 occasions reported at least 25% improvement in their other joints plus a feeling of systemic well-being following joint injection with triamcinalone hexacetonide. In seven of the 35 instances, 2 cc. or 40 mg. triamcinalone hexacetonide had been injected at one sitting, and in one instance a total of 3 cc. was given in multiple joints. It is difficult to escape the belief that significant systemic absorption has occurred in most of these patients. With this in mind the drug should be used with the precautions of potential overuse attending all adrenal corticosteroids, whether given locally or systemically.

Comparison with Hydrocortisone

The final feature of the study of the new compound was to compare its effectiveness with hydrocortisone t-butyl acetate. One hundred twenty-six trials were performed in 73 patients. A trial consisted of the observations associated with the injection of one cc. hydrocortisone t-butyl acetate (25 mg. hydrocortisone) or one cc. triamcinalone hexacetonide followed by a later injection of the alternate drug when the local signs of joint inflammation returned to their pre-injection state. Table 3 presents a summary of these observations. Both compounds gave an equally high percentage of initial "excellent" responses and in 25% of the trials this response was of equal duration for the two drugs. In 92 instances, or 73.6% of the total trials, triamcinalone hexacetonide had a 25% or longer duration of the local anti-inflammatory effect when compared with hydrocortisone t-butyl acetate. In 79 of these instances, or in 85.8%, this longer duration was by a factor of at least two, and in 54 trials, or 59.7%, the duration was at least three times longer with triamcinalone hexacetonide. Over all, the mean duration of effect was one month for hydrocortisone t-butyl acetate and three months for triamcinalone hexacetonide.

Summary and Conclusion

Triamcinalone hexacetonide, a new insoluble adrenocorticoid, was given 289 times

by intra-articular injection to 125 patients with active rheumatoid arthritis. In 267 trials, or 92.3%, a 90% or greater reduction in local inflammation was obtained, thus demonstrating an effect comparable to other reported cortisone analogs. However, in 141 trials, or in one half the injections, this local anti-inflammatory effect lasted for longer than three months. Transient local reactions occurred in seven instances (2.4%) and clinical evidence of systemic absorption followed

35 trials (12%). In a direct comparison with hydrocortisone t-butyl acetate in 73 patients and 126 trials, the new compound had a longer duration in 73.6% of the trials. The mean duration of local anti-inflammatory effect for hydrocortisone t-butyl acetate was one month, and for triamcinalone hexacetonide it was three months. Triamcinalone hexacetonide appears to offer a significant advance in intra-articular therapy in rheumatoid arthritis.

The Frontier Doctor — I

On the frontier a doctor was ranked with the schoolmaster, the minister and the judge. When he rode out to see the sick, boys lifted their hats to him and girls curtsied. In many parts of the West even the settlers' vicious dogs were not allowed to snap at the doctor as he cantered by. The physician was conceded the right to shoot a dog if he proved a nuisance. In the Far West bandits and rustlers let the doctor ride by unharmed. After all, a man never knew when he might desperately need his services.

All of this did not mean that the pioneer doctor was universally honored on the frontier, for there were many frontiersmen who hated him simply because he was an educated man. Some sniggered and repeated the popular saying, "The boy who goes into medicine is too lazy for farm or shop, too stupid for the bar, and too immoral for the pulpit."

— Richard Dunlop: *Doctors of the American Frontier*, Doubleday, 1965.

Abdominal Migraine Syndrome

Various writers have classified as a syndrome the symptoms of abdominal pain, nausea, vomiting, and sometimes diarrhea that are frequently a conspicuous part of the clinical picture of migraine (Brams, Blumenthal). The abdominal migraine syndrome is seen primarily in children or in adults who have had migraine for many years. Typical is a history of colic as a baby and a family history of headache or biliousness or both. Not infrequently the abdominal symptoms continue during childhood without attacks of headache, or may alternate in their occurrence with attacks of cephalalgia, or may continue after the headache has ceased. Parenteral administration of ergotamine usually causes prompt subsidence of symptoms. Desensitization with intravenous histamine affords more prolonged relief.

Restoration of Cerebral Physiology

An Unusual Case of Cardiac Resuscitation

LEROY EKSTRAND, M.D.*
Wabasha, Minnesota

DR. LEROY EKSTRAND'S report,** "Restoration of Cerebral Physiology: An Unusual Case of Cardiac Resuscitation," is of unusual interest for several reasons.

Not only is the case noteworthy because of the way the patient was treated and the results which followed, but it is an example of excellent medical practice in a small Minnesota community by a conscientious, knowledgeable physician, a member of a small professional group practicing in the community. Also, when hospitalization was necessary, the fine Community Hospital, St. Elizabeth's, with its nursing staff, assisted admirably in the care of the patient.

Dr. Ekstrand, with the assistance of Wabasha firemen whom he had trained in resuscitation methods, restored temporary cardiovascular function in two other cases. But both patients had been under water for an extended period of time, and cerebral damage was so severe from the anoxia that they died after eight to 14 hours of cardiovascular-pulmonary activity.

Dr. Ekstrand died last August from diffuse intestinal bleeding complicating a diffuse arteritis.

Waltman Walters, M.D.
Rochester, Minnesota

A 55-year-old white female school teacher had been feeling well until the night of April 22, 1965, when she awoke at 2 a.m. with severe substernal pain which radiated down both arms and was associated with shortness of breath. About half an hour later when seen in the home she was still having severe pain in the substernal area, but the pain seemed to be easing somewhat. At that time the patient's color was good and she was able to give a history which was typical of the pain of myocardial infarction. She had been hypertensive since 1961 and had been taking Diuril since that date. When last taken in the office, her blood pressure was 136 mm. Hg. systolic and 100 diastolic and she was taking Diuril, 500 mg. in the morning, and Eutonil, two tablets in the evening.

It so happened that this attack occurred during the time when the city of Wabasha was flooded, and in order to get the patient to the hospital she

*Community Clinic.
**Posthumous.

would have had to be transported by army truck across flooded roads. She was given 100 mg. of demerol, which made her fairly comfortable, and her husband was told to notify the physician if her symptoms became worse. About an hour later she began to have more pain; so an ambulance was summoned with the idea of taking the patient to the place where the ferry service with a truck could be used to transport her to the hospital. The ambulance driver and the physician arrived at the patient's side at about the same time.

The patient appeared moribund, pale, cyanotic, in cold perspiration, pulseless, and with only an occasional isolated shallow breath. She was unconscious and limp, but her pupils were not yet dilated.

Emergency Procedures

She was immediately removed from the bed to the floor where external cardiac massage and mouth-to-mouth respiration were begun. A plastic airway was inserted, and the patient's legs were elevated on a chair. While the ambulance driver, who was experienced at cardiac massage, continued the resuscitation, one ml. of Aramine was injected intravenously. After about five minutes of these efforts the patient seemed to respond favorably and started to breathe in gasps of about seven or eight per minute. However, no pulse could be felt when the cardiac massage was temporarily stopped.

On several occasions the respiration and color seemed to be improving so much that cardiac massage was stopped long enough to listen to the heart and feel for the pulse. When this was done the respiration deteriorated again, and no pulse or heart beat was evident until the massage was resumed. During massage a definite pulse could be felt with every pressure on the chest. Oxygen from the ambulance was then administered nasally. This seemed to improve the patient's color somewhat. External cardiac massage was used at a rate of about 40 per minute.

When the patient started to breathe spontaneously, an attempt was made to time the pressure on the chest so that it would occur between the inspirations. Soon the patient was breathing fairly well, but when the cardiac massage was stopped the respirations again deteriorated. After about 45 minutes of resuscitation, it was felt that if the patient could not continue on her own, further resuscitative measures would be futile. The cardiac massage was stopped; at this time a feeble pulse could be felt and the respirations were continuing. The pulse became stronger and quite regular. The blood pressure increased to 110/90, the color improved, and respirations became more normal. The patient was then transported to the hospital in an army truck with the oxygen going continuously. During the trip she remained unconscious and was perspiring profusely. She arrived at the hospital at 4:15 a.m. with a blood pressure of 100/60. At 4:45 a.m. she was moaning and restless with pain. After 0.5 ml. of Aramine was given intramuscularly, the blood pressure increased rapidly to 160/110, but subsequently the pressure decreased again to shock levels.

Hospital Management

On admission the patient was given sodium bicarbonate; heparin, 500 units every four hours intravenously; Aramine, 0.5 ml. intramuscularly as indicated (when systolic blood pressure was less than 100); and oxygen. Pulse, blood pressure, and respirations were followed closely. She was also given morphine sulfate, 1/6 grain, as indicated for restlessness, and penicillin, 500,000 units every 12 hours. She was catheterized so that the urinary output could be followed. The next morning she was semiconscious and in a cold sweat. The heart rhythm was irregular and the rate rapid. Breathing was easy. At 1:30 p.m. the blood pressure dropped to 80/70 and she was perspiring freely again. Levophed was given; this brought the blood pressure up to 110/80, and it was maintained at that level with the use of Levophed.

Results of laboratory tests on this day included the following: For blood, hematocrit, 47%; hemoglobin, 14.7 gm.; white blood cell count, 17,100. Urinalysis showed 4+ albumin and a trace of sugar; specific gravity was 1.020; reaction was acid; and the specimen was packed with white blood cells, epithelial cells, and some granular casts. The results of subsequent laboratory tests are given in the Table. The electrocardiogram of April 23, the day after the attack, showed many premature ventricular contractions, some occurring in runs and having varying foci from which they originated, Q waves, T waves, and ST shifts suggestive of massive myocardial infarction.

Progress

The next day she was able to open her eyes and smile and take water from a straw. The electro-

Cholesterol 131 mg/100 ml.

cardiogram was abnormal but showed improvement over the previous one. Her skin was warm and her chest was clear. She had a urinary output of 300 ml. Three days after admission she was taking water out of a glass and could smile and answer "yes" or "no." The fourth day she appeared brighter, and her blood pressure was staying above 100 mm. systolic without stimulants. Her chest was clear and her heart regular. That night she had to be catheterized again because of an overflow type of urination. An electrocardiogram on April 28 was compatible with recent, healing posterior myocardial infarction. Five days after admission she was able to read the headlines of the newspaper but was unable to tell who she was and was unable to give her husband's name. On the eighth day a foot drop was noted in the left foot. Urecholine had been necessary because the patient had been unable to void after catheterization, but on the twelfth day she was able to void on request.

End Result

After two weeks in the hospital she still had difficulty with her memory and was still unable to name her physician or even her husband. Three weeks after admission she was able to feed herself and carry on a fairly good conversation but was still unable to remember names or places. The blood pressure at that time was 116/80 and the pulse was regular, but the foot drop persisted. The electrocardiogram at that time showed a healing posterior infarct. A chest x-ray film was normal (the heart was of normal size and configuration). The patient stated that she would like to have visitors but felt embarrassed when she could not remember who the visitors were. Four weeks after the heart attack, results of bromsulphalein, phenosulfonphthalein, and cephalin-flocculation tests were all negative. The following week her memory was improving, and she could remember the names of her husband's five sisters. At that time she was fitted with a foot brace; before that she had had physiotherapy and other measures to bring back the strength in those

paralyzed muscles. An electrocardiogram on June 2 indicated healed or healing posterior infarct.

Six weeks after admission she was able to walk alone. After seven weeks she had no complaints, played all the nursery rhymes on the piano at home, but still had difficulty remembering names of people. Two months after her heart attack she was doing her own cleaning and housework. By three months after, she was getting movement in her left foot and was able to bring the foot up to a 90° angle with the leg. At that time she was able to discard the brace. She now has returned to her bridge club, and although she still has trouble remembering names she has no trouble playing bridge.

Summary

This was a case of a 55-year-old woman who had an acute myocardial infarct and either cardiac arrest or ventricular fibrillation and who was treated successfully in the home by means of external cardiac massage and mouth-to-mouth respiration. The important factors in this case which led to a successful resuscitation were thought to have been: (1) the insult being such that resuscitative measures were able to restore the partially wounded heart to beat again; (2) the promptness of treatment; (3) the presence of two persons trained in resuscitation; (4) the availability of nasal oxygen; (5) the use of an emergency airway; (6) the positioning of the patient with the head back and the legs elevated; (7) the early administration of Aramine; and (8) the continued attention in the hospital.

Patient and Doctor

When I was ill you came to me,
 Doctor, and with great urgency
 A hundred students brought with you
 A most instructive case to view.
 The hundred fingered me with hands
 Chilled by the blasts from northern lands!
 Fever at outset had I none;
 I have it, sir, now you have done!

Martial (43-102)

By a blessed dispensation, human beings forget physical pain much more quickly than they do their joyous emotions and experiences. A merciful Providence passes the sponge of oblivion across much that is suffered, and enables us to cherish the great moments of life and honour which come to us in our march.

— Winston Churchill, 1949

WHAT'S YOUR DIAGNOSIS?

A 35-year-old white female had been ill for approximately one week. On the second day of the illness, she had taken to her bed because of increasing weakness.

Her unsuccessful husband had not called a physician since there was no physician to call. Had a physician visited the patient, he would have found her in a rough, unfinished log cabin at Pigeon Creek, Indiana. He would have seen that her sick bed was a crude affair of poles stuck between the logs in a corner of the cabin, and that the cabin floor was dirt.

In taking the history, the physician would have learned that the patient loved milk and that one of the family's milk cows had died recently of the trembles. (These twin facts might or might not have impressed him as significant.) In inventorying the symptoms, he would have found that the patient had been ill for about a week with nausea, vomiting which was becoming increasingly intractable, malaise, obstipation, and an increasingly foul breath.

In the absence of a physician, the family cared for the patient as best they could. From her bed the sufferer could look out the door (for there were no windows) and see the riotously beautiful foliage in that autumn of 1818. Sick though she was, she must have enjoyed the panoply of colors — her last pleasure in a pitifully somber life.

Now, with a week gone by, she was becoming weaker and weaker. Feeling her life slipping away, she marshalled her waning strength and called her nine-year-old son to her. Fumbling with the boy's head as if to bless him, she told him in broken tones that he must always do right and be good to his sister and to his father.

A few more days and the patient was dead; she was borne in a rough-hewn cherry coffin to a wooded knoll about a quarter of a mile from the house and buried near the fresh graves of Mrs. Brooner, a neighbor, and Betsy and Thomas Sparrow, the patient's aunt and uncle — all of whom had died recently of the same ailment.

What is your diagnosis? Turn to page 495.

Pioneer Doctor's Fees

Charges for medical services varied. Dr. Drake said that the ordinary charge was 25 cents a mile, 'one half being deducted and the other paid in provender for his horse, or produce for his family.' In the earlier years the average country doctor would probably settle for 25 to 50 cents for a local visit, or a dollar if he sat up all night. The Indiana law of 1816 fixed fees at 12½ cents per mile of travel by day, double by night, but these fees were not strictly adhered to. Springfield, Illinois, physicians, for instance, agreed in 1840 to the following scale: daytime visit in town, \$1; up to four miles, \$2; each additional mile, 50 cents; prices double for night visits; verbal advice, \$1; each dose of medicine, 50 cents; vaccination, \$1; natural parturition, \$5 to \$10; fractures, \$5 to \$10; amputation of leg or arm, \$25 to \$100; lithotomy, \$100 to \$200.*

Duodenal Atresia and Maternal Hydramnios*

LOWELL W. BARR, M.D.
HARRY B. NEEL, M.D.
Albert Lea, Minnesota

ATRESIA** of the duodenum implies a lack of continuity at this level in the gastrointestinal tract. It is to be distinguished from stenosis in which there is a narrowing or stricture of the lumen. Duodenal atresia is a rare congenital condition which occurs once in 20,000 to 30,000 births. Obstruction may also be manifested by congenital diaphragms or multiple segments of stenosis. All of these defects develop during the sixth week stage of the embryo and are explained by a failure of the vacuolization and coalescence process that occurs in the solid cord state of this portion of the gut.¹ Duodenal atresia may be associated with atresia in other parts of the alimentary tract and with other developmental imperfections, such as harelip and cleft palate. A significant number of subjects with duodenal atresia are found to have Downs syndrome² or cystic fibrosis.³

Utero Signs

Hydramnios is an excessive quantity of amniotic fluid — usually over 1200-1500 cc. According to Ehrlich,⁴ who discussed the mechanism of hydramnios in duodenal atresia, a fetus normally begins to swallow amniotic fluid at the time kidney function starts, near the end of the fourth fetal month. If the swallowing act is delayed or absent, the fluid in the amniotic sac may be increased, leading to hydramnios. Such a delay also occurs in high obstruction of the alimentary tract, in which case the resorption of the amniotic fluid is missing. There is a definite correlation between hydramnios and congenital fetal malformations in which either the normal intrauterine deglutition or intestinal resorption is disturbed. These malformations include atresias and extrinsic or intrinsic obstructions of the upper alimentary tract. In fifty per cent of

*Presented at the Minnesota Surgical Society Meeting in Duluth on July 16, 1965.

**See Test Your Word Score Page 521.

the patients who develop hydramnios in the last trimester of an otherwise normal pregnancy, a fetal anomaly will be responsible for the hydramnios.⁵

Signs, Symptoms and Diagnostic Tests

The signs and symptoms of atresia are those of complete high intestinal obstruction. Vomiting begins soon after birth and

Fig. 1 — X-ray of Case 2 after giving gastrograffin by mouth. The greatly dilated duodenum appears as a round ball on the patient's right side.

Fig. 2 — Case 2. The dilated duodenum and the dilated stomach, separated by the pylorus, present an hour-glass appearance.

is persistent. Often large amounts of fluid may be obtained if the stomach is emptied by naso-gastric tube. Bile is usually seen but may be absent in the vomitus if the atresia occurs proximal to the ampulla of Vater. Abdominal distention, when present, is confined to the stomach and upper duodenum. Peristaltic waves may be seen traversing from left to right across the epigastrium. Stools may be absent or scant, dry and white.

Cornified epithelial cells which are desquamated from the skin of the fetus and swallowed with the amniotic fluid are present in normal meconium. The absence of these cells in the stool is presumptive evidence of intestinal or colonic obstruction. The stool specimen is smeared on a glass slide, stained with gentian violet and decolorized. The dye is removed from all cells except the cornified epithelial cells. This is known as Farber's test.⁶

The plain x-ray film of the abdomen is the most useful diagnostic aid. Air in the distended stomach and duodenum produces the "double bubble" or "hour-glass" effect, with absence of air in the intestine and colon. If a thin barium mixture or gastrograffin is instilled into the stomach, x-ray examination will reveal the greatly distended stomach and duodenum, with complete obstruction of the duodenum.

Surgical Treatment

Preoperative preparation and postoperative care form the cornerstone of treatment for these babies. The isolette provides a protective environment to permit adequate control of temperature, humidity and oxygen and allows adequate observation in the nursery. Suctioning and resuscitating equipment designed for infants should be readily available. Careful management of intravenous fluids and electrolytes requires well calibrated infusion sets. Intravenous fluids can be given by cut-down or by using small scalp vein sets; but because of the possibility of the late complication of extrahepatic portal-vein obstruction and portal hypertension, the umbilical vein should be avoided. Administration of fluids to newborns should be constantly monitored by the physician,

who should be alert to signs of over-hydration — puffy face or feet, tachypnea and tachycardia. Edema of prematurity must be taken into consideration and weighed against other evidence of over-hydration.

A basic solution of one part normal saline to four parts of 10% dextrose covers most needs of the newborn. Normal saline should be added to cover for gastric fluid lost by suction or vomiting. A safe amount of fluid in the first few days of life can be supplied by administering 50-60 ml./kg./24 hours if the baby is not dehydrated. By the fifth day the fluid requirement may total 100-150 ml./kg./24 hours.⁷

Prematures or infants may maintain water balance with as little as half these amounts if kept in high humidity. Sodium bicarbonate and potassium should be added, depending upon clinical findings and serum levels.

Blood should be typed and cross-matched for replacement during surgery, with a gastric tube in place during the operative procedure. General endotracheal anesthesia may be used, but local anesthesia may be satisfactory, especially in small or debilitated infants.

An anastomotic procedure to circumvent the atretic area is indicated. Duodeno-duodenostomy is the operation of choice, but gastrojejunostomy is satisfactory and is mandatory when the atresia involves the first portion of the duodenum. The entire length of the small bowel and colon should be examined for other areas of atresia.

Case Reports

Case 1

A 5-pound, 13-ounce boy was born to a twenty-seven-year-old woman as her eighth child on March 28, 1954. Moderate hydramnios was noted. The baby regurgitated all feedings but had small meconium stools. The vomitus was clear. The weight dropped to 4 pounds, 10½ ounces. Physical examination was negative except for dehydration and distention of the upper abdomen. Radiograph of the abdomen revealed a distended stomach and absence of air in the bowel.

On April 1, under local anesthesia, an upper right rectus incision was made. The stomach was tremendously dilated, the dilatation stopping abruptly at the duodenum which was atresic for a distance of about one centimeter. The cecum was adherent to the greater curvature of the stomach indicating incomplete rotation of the bowel. A

Fig. 3 — Case 3. X-ray of the abdomen made within an hour after birth. There is a bubble of air in the duodenum and a slightly larger bubble in the stomach. This is probably the earliest x-ray of the abdomen ever made in a patient with duodenal atresia.

Fig. 4 — Case 3. X-ray of abdomen made eight hours after birth. The characteristic "double bubble" sign is well demonstrated.

retrocolic gastrojejunostomy was performed. At the completion of the anastomosis the small bowel was distended by the gas which rushed into it.

Fluids and blood were administered through a cut-down, and feedings were begun cautiously on the third postoperative day. The patient did well and was discharged in four weeks, weighing 6 pounds, 3¼ ounces. He is now 12 years old and is normal in all respects.

Case 2

A woman, age 36 years, was admitted to the hospital on November 27, 1964, in strong labor. Previously she had had two Cesarean sections and an operation for tubal pregnancy. Under spinal anesthesia a low cervical Cesarean section was done and a 3-pound, 2½-ounce male infant was delivered. Hydramnios was noted. In spite of its small size, the infant cried at once and seemed quite vigorous, and the Apgar score was 10. Rales were heard in both lungs. The baby's stomach was aspirated and 45 cc. of fluid removed. No feedings were given by mouth and repeated aspirations were carried out.

On the second day antibiotics and intravenous fluids were started. X-ray of the abdomen revealed a moderate amount of gas in the stomach but absence of gas in the bowel distal to the duodenum. A gastrointestinal study with "gastrografin" revealed complete obstruction of the duodenum.

With a preoperative diagnosis of duodenal obstruction, operation was carried out the second day under local anesthesia. The stomach and first portion of the duodenum were greatly dilated, and beyond this area was a segment of atresia. A duodeno-duodenostomy was performed and the operation well tolerated. Bowel sounds were active on the day following operation and feedings of small quantities (10 cc. every two hours) were started. On the fifth day the patient had several stools. Feedings were increased and were retained. On December 5 the baby was tolerating feedings, and there were active bowel sounds. Feedings were then increased, and on the tenth postoperative day full strength feedings were given. However, the rales in the chest persisted. Respiratory distress slowly increased and an x-ray of the chest showed heavy bilateral bronchopneumonia. The baby's condition gradually deteriorated and he expired on the fourteenth postoperative day. At post mortem, the duodeno-duodenostomy was functioning well. There was severe bilateral bronchopneumonia. The cause of the pulmonary disease was comparable to that seen in some infants with cystic fibrosis.

Case 3

On July 10, 1965, a 5-pound, 8-ounce male baby was born to a 45-year-old woman as her fourth child. The delivery was vaginal, and hydramnios, estimated to be over 3000 cc., was present. The baby breathed spontaneously but appeared to be mongoloid. The Apgar score was 10. Soon after birth the baby spit up amniotic fluid, and repeated gastric aspirations yielded 30-35 cc. of bile-stained fluid. X-rays of the abdomen at one hour and at eight hours of age showed the typical double bubble of duodenal atresia. A barium enema

showed a normal colon. Surgery was done under local anesthesia at 18 hours of age. The stomach and first portion of the duodenum were greatly dilated; the jejunum and ileum were empty. A duodeno-duodenostomy was carried out. X-rays taken on the fourth day showed a passage of gas through the anastomosis, and the baby tolerated feedings. With apparently normal gastrointestinal function the baby has done well.

Discussion

Surgery offers the only hope of survival and should always be done. Although, Ernst⁸ performed the first successful operation for relief of duodenal atresia in 1914, many years elapsed before there were reports of other successful attempts. In 1931 Webb and Wangenstein⁹ stated that there had been only nine operative triumphs up to that time and that their two efforts had ended in failure. Nevertheless, successful management of an infant with atresia of the second portion of the duodenum associated with complete biliary obstruction was not reported until 1960.¹⁰ Not until 1953 did Gross¹¹ report on the operative treatment of thirty-two cases.

Glover and Barry,¹² in 1949, reported a mortality of 75% in the treatment of patients with complete intestinal obstruction. According to Evans,¹³ prior to 1951, only 139 patients with intestinal atresia had been successfully treated and reported. More recently Gross¹¹ reported a mortality of 50% in patients with duodenal atresia. In a 1963 symposium Dr. Tague Chisholm¹⁴ commented on the survival of infants with intestinal obstruction requiring surgery: "of term infants with no other major anomalies, three fourths are surviving today with present management, whereas, 20 years ago, three fourths of these infants died; but with premature or term babies who have associated serious anomalies, the record is rather disheartening — with only about 25 percent surviving." The causes of mortality are associated anomalies, prematurity, delayed operation, inadequate supportive therapy, operative indecision, cystic fibrosis and chest complications.

Summary

1. Duodenal atresia is a rare congenital

condition which occurs once in 20,000 to 30,000 births.

2. Hydramnios is a frequent accompaniment of duodenal atresia and its presence should arouse suspicion of an obstructed duodenum.

3. Surgery offers the only prospect of cure. A circumventing procedure, preferably a duodeno-duodenostomy, is indicated and should be attempted in all cases.

4. Early diagnosis, preoperative and post-

operative care are the cornerstones of successful treatment.

5. The mortality following operative treatment fluctuates between 25% and 75%. Prematurity, associated anomalies, and chest complications contribute to the mortality.

6. Mongolism is present in 20-30 percent of cases of duodenal atresia.

7. Cystic fibrosis is present in one fourth of cases of duodenal atresia.

8. Three cases of duodenal atresia with maternal hydramnios are presented.

ANSWER TO WHAT'S YOUR DIAGNOSIS (From page 490).

The patient was Nancy Hanks Lincoln — Abraham Lincoln's mother. The cause of her death was milk sickness.

Unfortunately, the general tendency of things is to render mediocrity the ascendant power. At present, individuals are lost in the crowd, and it is almost a triviality to say that public opinion now rules the world. And public opinion is the opinion of collective mediocrity and is expressed by mediocre men. The initiation of all wise and noble opinions must come from individuals, and the individuality of those who stand on the higher eminences of thought is necessary to correct the tendency that makes mankind acquiesce in customary opinions.

— John Stuart Mill

In your relations with people it is necessary to try to give them as much as possible and to take from them as little as possible. — Tolstoy

Dr. John Richmond

In Newton, Ohio, in 1827, Dr. John Richmond performed the first recorded Caesarean section west of the Alleghenies. Some idea of the magnitude of his task might be obtained from his own report:

"I had no recourse to cordials, for these could not be obtained. I was seven miles from home, and had but few medicines with me. . . . I requested advice, which, however, could not be obtained, on account of high water in the Little Miami and the darkness of night. . . . After doing all in my power for her preservation, and feeling myself entirely in the dark as to her situation, and finding that whatever was done, must be done soon, and feeling a deep and solemn sense of my responsibility, with only a case of common pocket instruments, about one o'clock at night, I commenced the Caesarean Section. . . . The night was stormy and windy, insomuch, that the assistants had to hold blankets to keep the candles from being blown out. Under these circumstances it is hard to conceive of the state of my feelings, when I was convinced that the patient must die, or the operation be performed. . . . The patient never complained of pain during the whole course of the cure. She commenced work in twenty-four days from the operation, and in the fifth week walked a mile and back the same day."*

Laughter

"Why is laughter so pleasant?" asked someone.

"Because," someone answered, "laughter relieves us of superfluous energy, which, if it remained unused, might become negative, that is, poison. We always have plenty of this poison in us. Laughter is the antidote. But this antidote is necessary only so long as we are unable to use all the energy for useful work. It is said of Christ that he never laughed. And indeed you will find in the Gospels no indication or mention of the fact that at any time Christ laughed.

"But there are different ways of *not* laughing. There are people who do not laugh because they are completely immersed in negative emotions, in malice, in fear, in hatred, in suspicion. And there may be others who do not laugh because they cannot have negative emotions. Understand one thing. In the higher centers there can be no laughter, because in higher centers there is no division, and no 'yes' and 'no.' "

Regional Circulation in the Brain Using a Scintillation (Anger) Camera

DYNAMIC STUDIES of isotope distribution in the body are at present being made possible by the use of gamma camera instruments. This report summarizes some preliminary trials with a scintillation (Anger) camera|| which is being used to study the distribution of blood within the human brain. The ultimate aim of the present study is to develop a method by which data on regional cerebral circulation may be accumulated in a rapid fashion in order to diagnose localized abnormalities of blood flow to the brain.

Principle

The clearance techniques as previously reported for studying the regional cerebral blood flow are based upon a recording of the wash-out curve of a freely diffusible isotope over a period of 10 to 15 minutes. The clearance curve is then a function of the blood flow.^{1,2} In the present study we have utilized a modification of the bolus fractionation technique of Sapirstein.³ This technique assumes that blood going to the brain is suddenly labelled at a uniform concentration with an indicator which is quantitatively retained at the tissue level, such that each tissue component will accumulate radioactivity in proportion to its blood flow. Pre-supposing iso-efficiency counting, the differences in externally measured radioactivity will be proportional to differences in blood flow. This means that the gamma camera will "see" areas of different intensity of radioisotopic pickup which will then be directly proportional to the blood flow to the different parts of the organ visualized

on the two-dimensional display of this instrument. It is possible to combine this use of the "bolus fractionation" technique with the above mentioned isotope clearance technique, i.e., to record radioactivity during the clearance phase and from these data determine regional blood flow in quantitative terms of ml/g/min.

The Tracer

Bolus-Fractionation Technique

The principle involved in the bolus-fractionation technique is perhaps best conceptualized by considering the use of a radioactive macrocolloid injection at the aortic root. If the extraction of the isotope from the blood is 100 per cent during the first passage through the peripheral vascular bed, then clearly the isotope uptake in the different organs will correspond to the distribution of blood flow. As the retention of a macroaggregated tracer such as 99m technetium albumin is of hours' duration, instruments requiring considerable time for image formation, e.g., scanners, can be used effectively for obtaining high resolution scintiphotograms. This technique is presently being used to good advantage for studying pulmonary circulation in numerous radioisotope clinics. Due to the possible risks of ischemic tissue damage in the brain this type of indicator is in principle less attractive than a freely diffusible inert radioactive gas such as 133-xenon.^{4,5}

Diffusible Inert Indicators

Freely diffusible inert indicators move rapidly out of the capillaries, depending upon concentration differences between the blood and surrounding tissues. The initial extraction from the blood of these indicators into the tissue during the first capillary passage is therefore very high, approaching 100 per cent, since diffusion equilibrium is believed to occur in less than one second.⁶

*It is not possible to use hydrophilic radioactive ions such as 42-K or 86-Rb for brain blood flow studies since the blood brain barrier is normally almost impermeable to crystalloids.⁷ (This is mentioned here since for other organs, such tracers might be used in accordance with the Sapienstein principle under discussion.)

**Since this instrument can record only a single emission event at any one instant, there is an interval, albeit in the micro-second range, between each recorded emission. This interval is called the "dead-time."

These lipophilic freely diffusible tracers* are of two types:

NON-VOLATILE: Iodo-antipyrine is the most widely used indicator of this type.

VOLATILE INDICATORS: The extremely short biological half-life of inert gases such as 85-Kr or 133-Xe makes it possible to administer rather large quantities of radioactivity to patients without significant radiation hazard. Calculation shows that an intravenous or intra-arterial injection of 40 millicuries of xenon-133 dissolved in saline results in a gonadal dose of about 10 millirads — which is about 2 per cent of the gonadal dose from an ordinary x-ray film over the pelvis and a level considered safe for routine diagnostic isotope work.* Such doses of these radioisotopes would result in counting rates which are considerably higher than can optimally be recorded by any gamma camera device available at the present time. It is concluded therefore that, in practice, the upper limit for the activity of 133-xenon used is governed more by the resolving characteristics of the instruments used than by the radiation dose to patients.

Radioactive Gas

Of the many radioactive gases which exist, 133-xenon appears at present to be the most promising. It is readily available and has a half-life of 5.27 days and a gamma emission of 81 Kev. which is suitable for localization studies with instruments presently available. This is particularly true for our scintillation camera in which bialkali cathode phototubes have been installed. The lower work function for electron release in these phototubes permits improved resolution in studies employing radioisotopes such as 133-xenon which emits relatively low energy gamma photons.

With the use of 5-10 millicuries of 133-xenon, very high counting rates are to be expected, so that the "dead-time"*** of the recording instrument should be maintained at an absolute minimum. Recent circuitry modifications have decreased the dead-time for our scintillation camera to about 4 microseconds which appears to be about

the best obtainable with an instrument of this design but sufficiently good to permit pictures of isotope distribution to be obtained at intervals approaching one second.

Intra-Arterial Injection of 133-Xenon

By slug injection of 133-xenon dissolved in saline via the internal carotid artery only the brain receives the radioactive indicator. This is obviously a major advantage over a common carotid artery or other injection in which the radioisotope may be taken up in other tissues. Slug injection refers to the administration of a small amount of the radioisotope solution, about 2-5 milliliters, in about one second. This rapid injection implies that the period during which the isotope distribution is a function of flow is very short, being in the order of about 8-10 seconds. Following this time the initial high uptake of 133-xenon in high flow regions will decrease due to wash-out by non-labelled blood. The briefness of such a study necessitates that a relatively large dose of 133-xenon, about 10 millicuries, must be used in order to accumulate enough counts during the 0.1-0.3 minutes available for several serial photographs to be taken.

Internal Carotid Artery Injection of 10 Millicuries of 133-Xenon

A 67-year-old patient, with hemiparesis secondary to a stroke syndrome, received an injection of 10 millicuries of radioactive xenon gas dissolved in saline. This study was performed before high speed circuitry was added to our gamma camera so that it is very evident from the pictures obtained that the resolution was very poor, due to overloading. Figure 1 is the first picture in a series obtained and demonstrates the passage of the bolus up the carotid artery. It is readily appreciated that this picture demonstrates much less resolution than obtained from an "arterial phase arteriogram" which ideally might be expected and indicates the need for improvement in resolution of gamma camera systems.

Prolonged injection at a constant rate (or perhaps with a slightly increasing speed over 0.5 to 1.0 minutes) solves the difficulty of the very brief "filling-up" period but does

not provide clearance data from which cerebral blood flow may be calculated.

Common Carotid Artery Injection of 4 Millicuries 133-Xenon

Injections into the common carotid artery can also be made according to both methods referred to above, i.e., with the bolus technique or with a prolonged injection. However, this leads to substantial "contamina-

Fig. 1 — This scintiphotogram was obtained during the first 5 seconds after the administration of 10 mc. of 133-xenon in saline via catheter in the right internal carotid artery. This right lateral projection shows gross distribution of the radioactivity extending from the internal carotid artery throughout the right hemisphere.

Fig. 2 — This right lateral scintiphotogram was obtained immediately following the administration of 4 mc. of 133-xenon in saline via the common carotid artery. Exposure time was 10 seconds. The radioactivity is seen to be present in structures perfused by the external carotid artery as well as that part of the brain perfused by the internal carotid artery. It may be noted that there is very little uptake in the posterior fossa.

tion" of the picture by the ^{133}Xe arriving into the field via the external carotid artery⁹ (Figure 2). The patient for this study was a 62-year-old man with left hemiparesis and confusion. Injection of the isotope into the common carotid artery showed highly blurred pictures due to large amounts of isotope in the face area and the

Fig. 3 — This scintiphotogram was obtained using 4 mc. of ^{133}Xe in saline injected into the right common carotid artery. This is a right lateral view with an exposure time of 20 seconds. A lead shield was placed over the face. There is an area of decreased intensity in the centro-parietal region which corresponds to a slow wave EEG focus and to what was thought clinically to be an area of infarction. Another scintiphotogram obtained later in the series failed to show this area of decreased intensity.

Fig. 4 — These scintiphotograms of the right lateral and anterior projections of a patient were obtained two hours after the intravenous administration of 10 mc. of $^{99\text{m}}\text{Tc}$ (pertechnetate). There is a focus of radioactivity in the right frontal area (shown by arrows) which represents metastatic spread of a breast carcinoma.

air ways. Of interest is the absence of counts in the posterior neck region not supplied by the common carotid artery.

This study was repeated with a lead shield over the face. The resolution was better, and there is a small area of relatively few counts in the midportion of the hemisphere where large numbers of counts should be expected (Figure 3). This likely represents an ischemic lesion corresponding to the patient's symptoms and the focal abnormality in an EEG tracing.

Inhalation or Intravenous Injection of ^{133}Xe

For ^{133}Xe inhalation studies the patient breathes from a spirometer containing about 5 liters to which 5-10 millicuries of the radioactive gas has been added. A lead shield is used over the facial structures as has been described for common carotid artery injections. A blood pressure cuff has also been used around the base of the skull to eliminate "contamination" from radioactivity via the extracerebral arteries.

Inhalation of ^{133}Xe

The patient was a 40-year-old woman with a metastatic brain tumor in the right frontal region as seen by a $^{99\text{m}}\text{Tc}$ study (Figure 4). During the initial portion of the inhalation period of four minutes, a definite region of low uptake could be seen which appeared to correspond to the location of the tumor (Figure 5). This regional uptake difference was not appreciated on later pictures and demonstrates how the isotope distribution changes during the clearance phase. Thus the initial regional differences in perfusion observed during the bolus fractionation period tend to be lost.

Intravenous Administration of ^{133}Xe

After an intravenous injection, the isotope must first pass through the lungs before reaching the brain. Since much activity will be lost in this process, solutions of relatively high activity must be used. Except for this fact, the intravenous study would be essentially identical to the inhalation study without the complication of a spirometer, mouth piece, etc. From a general

clinical standpoint the intravenous administration would seem to offer an attractive alternative to the inhalation route.

The patient in this study was a 65-year-old man with a cerebral hemorrhage followed by complete aphasia and right-sided hemiplegia. The gamma camera pictures following administration intravenously of 10 millicuries of ^{133}Xe in 5 milliliters saline showed just a bare suggestion of radioisotope uptake in the left hemisphere (the parieto-occipital area). The initial pictures in this series showed minimal uptake in the airways which are always clearly visualized on the inhalation studies. This indicates another potential advantage of intravenous administration of ^{133}Xe over its being inhaled.

Administration of Iodoantipyrine

One patient in our series received an intravenous injection of 1.5 millicuries of ^{131}I -iodoantipyrine. This study revealed that this indicator is not suitable for cerebral circulation studies with the scintillation camera. The scintiphotograms of the head of this patient were extremely blurred and no contours of concentration differences could be discerned.

Discussion

Results of studies shown in the last section indicate the limitations of the scintillation camera for pictorial representation of regional cerebral blood flow. Two improvements were made during the course of these studies which have significantly improved the resolution of this system. The first of these was the insertion of bialkali phototubes with lower work functions than photo multiplier tubes heretofore available. This has meant greater efficiency in the detection of relatively low energy gamma rays as well as better correlation between the position of the scintillation event in the crystal and its position on the scintiphotogram. A second important improvement has been the modification of the electronics to permit a more rapid accumulation of data. Consideration is now being given to changes in collimator design and possibly the use of

a thinner crystal, particularly for low energy gamma emitters.

Carotid Isotope Injections

In general, carotid isotope injection studies are hampered in their interpretation by the fact that one can never be sure, without angiographic studies, what areas an individual artery will supply. A region of low uptake will not necessarily mean a region of low blood flow. It could represent a region supplied by an artery other than the one injected. An extreme example would be that of a thrombosis of the common carotid artery on one side. With adequate collaterals from the vertebrals and other vessels, the area normally supplied by the occluded vessel may have normal blood flow despite the fact that no ^{133}Xe can be deposited intracranially following injection into the carotid artery proximal to its occlusion. Flow in this case could be explored by injecting the isotope into one of the vessels supplying the collateral flow, for example, the contralateral carotid artery. This technique will then offer an approach to evaluating the effect of carotid occlusive lesion.

Fig. 5 — This right lateral scintiphotogram was obtained using ^{133}Xe administered to the same patient whose brain study is shown in Figure 4. The ^{133}Xe was administered by inhalation from a spirometer containing approximately 10 mc. of xenon in 5 liters of air. A lead shield was used to eliminate the pick-up of radioactivity from the muscles of the face and other areas perfused by the external carotid artery. This scintiphotogram gives the impression of a decreased uptake of ^{133}Xe in the area of the metastatic lesion. Right lateral scintiphotograms obtained later in the course of inhalation of the ^{133}Xe and also during its clearance phase did not show this apparent decrease in activity in the region of the metastatic lesion.

Some improvement in the common carotid injection technique is derived by the use of a suitable blood pressure cuff applied around the skull during the injection phase of the study. By inflating this cuff above systolic pressure, "contamination" of the gamma camera picture by radioactivity in tissues perfused by the external carotid arteries is significantly reduced.

The initial pathophysiological process in apoplexy is undoubtedly localized ischemia, i.e., local deficiency of blood flow. In such an area one must expect to find an absence or a diminution of isotope uptake when the isotope is administered in one of the ways described above. However, we know that these localized areas of ischemia often lie deep within the cerebral hemisphere so that other projections, e.g., coronal, may be desirable in order to graphically demonstrate the ischemic focus.

Vascular Brain Lesion

In this context it should be pointed out that a localized vascular lesion in the brain will affect the whole brain rather markedly. Regional measurements of cerebral blood flow in typical focal vascular cerebral disorders have usually shown a general decrease of the blood flow, not only in the area of infarction, but also in areas which are clinically and angiographically normal.¹⁰ This "remote" effect of the focal lesion will, in studies of the present type with the gamma camera, lead to a diminished contrast between the lesion and the normal surrounding brain.

Ischemic Focal Lesion

In an ischemic focal lesion the diminished focal flow may not persist, since the underlying obstacle for the blood flow may be relieved by an increase in perfusion pressure, by lysis of an embolus, or by the take-over of collaterals. The flow may return to normal or nearly so within the lesion even if the localized symptoms persist because of cellular damage. It is even quite likely that, in part, a hyperemia may develop due to the uncoupling of the normal vasoconstrictor tone of the cerebral vessels. There is some angiographic evidence for such a hyperemic

zone around local vascular insufficiency areas in the brain.¹¹ This hyperemic zone would, naturally, show up in isotope studies of the present type as areas of increased uptake.

It should also be pointed out that, in principle, it is much more difficult to record a "negative" picture than one that is positive. A study of the present type which aims at picturing differences and abnormalities in blood flow yields a negative shadow and should therefore be correlated when possible with "positive" scintiphotograms obtained following administration of 99m technetium or 197 mercury chlormerodrin to patients suffering from vascular lesions causing cerebral infarction.

Inhalation Approach

Our experience thus far indicates that the inhalation approach to administration of 133-xenon for cerebral blood flow studies shows considerable promise. For these inhalation studies approximately 5 to 10 mc. of 133-xenon is placed into a spirometer system. The patient breathes the xenon-air mixture from this system which is so arranged that oxygen is added to compensate for the carbon dioxide which is continuously removed. The time of breathing in this manner is usually restricted to three minutes in order to maintain a small radiation dose to the patient. This is usually sufficient time for the xenon to reach equilibrium in the patient. In individuals with some form of pulmonary disease, we find that the equilibrium has not been reached in this time and consideration is being given to longer breathing times for these patients. The effect, if any, of the spirometer breathing time *per se* on the clearance curves is being investigated. A lead shield is being used over the facial structures to mask out xenon activity in extracranial tissues, as was described for common carotid artery injections. An inflatable cuff is being used around the base of the skull to eliminate, insofar as possible, "contamination" from radioactivity arriving via the extracerebral arteries. A lead shield is also being used to eliminate xenon activity in respiratory passage ways as well as other extracranial tissues.

During the clearance period which follows the uptake, there is a redistribution of the radioisotope as it clears body tissues. This complicates the analyses of curves relating to xenon clearance from the brain, particularly in individuals with pulmonary disease. Our present protocol for evaluation of cerebral blood flow following inhalation of 133-xenon therefore includes corrections for clearance of 133-xenon from extracerebral tissues and for the small percentage of 133-xenon which is not cleared in one passage through the lungs and thus returns to the systemic circulation.

Results

The results of our single study with iodoantipyrine left much to be desired. The reasons for the poor success in this particular study are: (1) The 364 Kev. photopeak of 131-iodine is well above the energy range for which the scintillation crystal is most efficient. (2) The complex spectrum of 131-iodine, which includes high energy components and consequently contributes to significant scatter. (3) The level of radioactivity in the brain remains low. A total count recorded over the first 15 seconds was only 2500, which was much too low to permit adequate resolution on a scintiphogram. It is concluded from the study with iodoantipyrine that one would need to use on the order of 200 millicuries of this radioisotope to obtain reasonably good pictures. Such high doses cannot be used routinely due to the long effective half-life and hence radiation hazard of the isotope in question.

Considerations for Improvement

Our ultimate aim is to be able to quantitate regional cerebral blood flow. As an initial step in this direction, we have modified

our scintillation camera to permit graphic recording of data from each data of radioactive uptake and clearance from each cerebral hemisphere. Our next step will be to utilize computer analyses of the curves obtained in this way.

An obvious extension of this would be to obtain curves representative of regional cerebral blood flow. We are contemplating the use of automatic time lapse photography with a movie camera to record in sequence the changing pattern of radioactivity as displayed by the cathode ray tube read out of the scintillation camera. The serial pictures obtained in this way should permit a qualitative analysis of total and regional cerebral blood flow. A flying spot scanner might be used to analyze the distribution of radioactivity on the time lapse pictures obtained in such a way that computer analysis of the data obtained might be contemplated. An alternative plan which is being considered is to utilize video tape to record the changing pattern of radioactivity as seen on the oscilloscope read out. This tape might then be played back through a television system and an analysis made of any desired cross-sectional areas as represented on the television screen. The data obtained in this way may again be processed for computer analysis.

Once the techniques have been established we are hopeful of studying routinely all stroke or potential stroke patients. The effect of vasodilators, etc., on cerebral blood flow will be investigated. In this way each patient may serve as his own control. Patients will also be studied before and after surgical correction of arterial occlusions to better evaluate changes in cerebral blood flow related to the surgical procedure.

Whence?

Do we bring our souls into the world, or are they evoked by circumstance?

— George Moore

Aphorisms of Maimonides

(1135-1204)

Part II*

13. Special care should be taken to have regular movements of the bowels that carry off the impurities of the body. For this purpose young people should be given salty food, materials that have been soaked in olive oil, salt itself, or certain vegetable soups with olive oil and salt. Older people should take honey mixed with warm water early in the morning and four hours later should take their breakfast.

14. Another axiom of medicine is that so long as a man is able to be active and vigorous, does not eat until he is over-full, and does not suffer from constipation, he is not liable to disease.

15. Immoderate eating is a poison for men and the cause of many diseases which attack them. Most diseases come from either eating too much or partaking of unsuitable food. That was what Solomon meant with his proverb: "He who puts a guard over his mouth and his tongue protects himself from many evils," that is to say, whoever protects his mouth from the over-indulgence in food and his tongue from unsuitable speech protects himself from many evils.

16. Every week at least a man should take a warm bath. One should not bathe when hungry, nor after eating until the food is digested, and bathe the whole body in warm but not too hot water and the head in hot water. Afterwards the body should be washed in lukewarm and cool water until finally cold water is used. One should pour neither cold nor even lukewarm water on the head, nor bathe in cold water in the winter time, nor when the body is tired and in perspiration.

17. As soon as one leaves the bath one should cover oneself, and especially cover the head, so that no draught may strike it. After this one should rest for a while until the heat of the body passes off and then should go to table. Neither during the bath nor immediately after it should cold water be drunk, and if there is an unappeasable thirst a little wine and water or water and honey should be taken.

18. Venesection should not be practiced frequently, for it is only meant for serious illness. After passing his fiftieth year an individual should abstain from venesection. Venesection should not be practiced on the day when one takes a bath or goes on a journey or returns from it. On the day when it is practiced less than usual should be eaten and drunk, and the patient should give himself to rest, undertake no work nor bothersome occupation, and take no walk.

19. Whoever observes these rules of life faithfully I guarantee him a long life without disease. He shall reach a good old age, and when he comes to die will not need a physician. His body will remain always strong and healthy, unless of course he has been born with a weak nature, or has had an unfortunate bringing up, or should be attacked by epidemic disease or by famine.

20. Only the healthy should keep these rules. Whoever is ill or a sufferer from any injuries, or has lost his health through bad habits, for him there are special rules for each disease, only to be found in the medical books. Let it be remembered that every change in a life habit is the beginning of an ailment.

Benign and Malignant Gastric Ulcers

Diagnostic
Accuracy
X-ray
Examination
in
Differentiating*

JOHN BARTNESS, M.D.
Albert Lea, Minnesota

THE PREHISTOLOGICAL differentiation of benign and malignant gastric ulceration has long been a medical enigma. Up to the present time there is still no completely infallible method of differentiation. Brown et al.¹ concluded from their study of 106 cases of malignant gastric ulcer that no clinical symptom is specific in any way for carcinoma.

The purpose of this study was to determine the accuracy of the latest methods of roentgenological examination combined with meticulous scrutiny of the gastric mucosa by the examining roentgenologist.

Materials and Methods

One hundred fifty consecutive cases of gastric ulcer diagnosed by x-ray over a three-year period from mid-1963 to mid-1966 were reviewed. In all cases either x-ray or surgical follow-up studies were made. There were 88 male and 62 female patients. The youngest was 15 and the oldest, 89 years. The average age was 54.3 years. Because the study was concerned primarily with the accuracy of present methods of roentgenological diagnosis and directed rather rigidly at the morphological characteristics of the ulcer and surrounding mucosa, history, physical examination, laboratory studies, or any other factor which might influence the x-ray diagnosis, was not taken into consideration. Image intensification and cineradiography were used routinely on all patients. A nine-inch mirror and closed circuit television with magnification switch were used interchangeably. Anteroposterior, lateral, and posterolateral radiographs as well as spot films were made on every patient.

In each case the pliability of the gastric mucosa immediately adjacent to the ulcer crater, as well as the more distant mucosa,

*Presented at the Annual Meeting of the Southern Minnesota Medical Association, September 16, 1966, in Austin, Minnesota. Received annual award for the most outstanding paper presented at the time.

was noted and the morphological characteristics of the crater, of the edges of the crater, and of the surrounding mucosal pattern, were very carefully examined. Since almost all stomachs contain swallowed air, an automatic double air contrast study was easily obtained in the majority of patients by placing them in the supine position. This double air contrast effect is very clear when viewed directly with image intensification and indirectly with cineradiography, and was extremely helpful in increasing the clarity of the ulcer margins and the detail of the adjacent mucosa.

Nature of the Ulcers

Most of the ulcers were found in the lesser curvature of the antrum. See Table 1 for details.

TABLE 1

Lesser curvature of the pars media	45
Greater curvature of the pars media	4
Lesser curvature of the antrum	86
Greater curvature of the antrum	8
Prepyloric	6
Lesser curvature of the cardia	1

Size of Ulcers

The ulcers varied in size from 1.5 mm. to 5 cm. The size of the ulcer also had no bearing on the radiological diagnosis.

Associated Duodenal Ulcer

Thirty patients had accompanying duodenal ulcers. However, this did not influence the study in any respect. Lampert et al.² found in their study of malignant gastric ulcers that 21.9 percent had accompanying duodenal ulcers.

A statement as to whether the ulcer was benign or malignant from an x-ray standpoint was included in the x-ray report of each patient. If the ulcer was thought to be radiologically benign, repeat x-ray studies were done following two to ten weeks of medical management. Gastric ulcers were considered proven benign if follow-up x-ray studies revealed that the crater and any edema of the adjacent mucosa had completely disappeared. Meireles et al.³ have concluded from a study of 250 gastric ulcers,

that a gastric ulcer which disappears completely with obliteration of the crater and no evidence of stiffening of the adjacent gastric wall may be safely accepted as benign.

Results

Of 143 gastric ulcers labeled benign on x-ray examination, all 143 were found to be benign by follow-up x-rays or surgery.

Case One

In one patient, a 59-year-old white female, a 2.5 cm. ulcer crater was demonstrated on the greater curvature of the antrum. A second ulcer, slightly smaller, was found on the lesser curvature of the pars media of the stomach. Both ulcers were called radiologically benign. The examination was repeated six weeks after medical management. Both ulcers had increased in size but were again labeled benign by x-ray examination. A third examination was done three months after continued therapy. The ulcers remained the same in size but were again called radiologically benign. A gastric resection was performed and both ulcers were found to be histologically benign.

Case Two

A 50-year-old female was found to have an ulcer crater 3.5 cm. in diameter located on the greater curvature of the antrum. The ulcer revealed no radiographic characteristics of malignancy. Three subsequent examinations at six-week intervals failed to show any change after medical management and the ulcer was still diagnosed as benign by x-ray. Surgical exploration and gastrectomy were performed and the ulcer declared histologically benign.

The Malignant Ulcers

Four gastric ulcers which were called malignant on x-ray examination were found to be histologically malignant following surgical removal. Stiffness of the mucosa adjacent to the ulcer crater and intraluminal hypertrophy of the margins of the crater (Carman's meniscus sign) with minimal mucosal edema were demonstrated in two of the cases. A third case revealed a broad, shallow ulcer crater with stiffness of the mucosa around it and a small degree of prominence of the edges of the crater. The ulcer of the fourth patient was 1 cm. in diameter and located on the greater curvature of the antrum. No decision was made on the first examination; however, on repeat examination a vague lack of pliability of the mucosa around the ulcer was noted. In addition, edema with spasticity was demonstrated

throughout the antrum probably due to concomitant antral gastritis.

The Suspiciously Malignant Ulcers

The three remaining cases in the study were called malignant from a radiological standpoint but were proven to be benign. One was a 50-year-old male with an ulcer crater 3 cm. in diameter on the greater curvature of the pars media. The crater was shallow, showed minimal elevation of the ulcer margins, and stiffening of the crater itself as well as the surrounding mucosa. Surgical exploration revealed a benign gastric ulcer with chronic perforation into the body of the pancreas. Histological specimens revealed considerable localized chronic inflammatory reaction. A second case showed definite intraluminal building-up of the margins of the crater. Subsequent surgery revealed a benign ulcer. Although building-up or hypertrophy of the ulcer margins may be extremely helpful and arouses the suspicion of malignancy, it is not a pathognomonic sign in differentiating benign and malignant gastric ulcers. Nevertheless, it is felt that such cases should be surgically explored. The last patient, a 65-year-old female, had a greater curvature antral ulcer with mucosal edema and elevation of the ulcer margins. Although there was no demonstrable mu-

cosal stiffening, surgical exploration was advised because of the intraluminal hypertrophy of the ulcer margins. Surgery was deferred because of a cardiac condition and re-examination by x-ray four weeks following a semi-ulcer diet revealed that the ulcer had completely disappeared.

Conclusions

The purpose of this study was to determine the accuracy of the latest methods of roentgenological diagnosis in differentiating benign and malignant gastric ulcers. One hundred and fifty consecutive cases of gastric ulcer diagnosed by x-ray over a three-year period were included in the study. One hundred and forty-three gastric ulcers were called benign on x-ray examination and were proven to be benign by follow-up x-rays or surgery. Four gastric ulcers were labeled malignant on x-ray examination and all four were found to be malignant following surgery. Three gastric ulcers were diagnosed as malignant by x-ray and were found to be benign by follow-up x-rays or surgery.

The refinement of current methods of roentgenological examination and the adaptation of the radiologist to these methods are believed to be significant factors in lessening the percentage of error in differentiating benign and malignant gastric ulcers.

Ten Commandments for Doctors

1. Don't keep your patient waiting.
2. Discuss your fee frankly with him.
3. Explain disease and treatment to him.
4. Let the patient talk.
5. Don't ask the impossible of him.
6. Don't divide your attention.
7. Know his family.
8. Tell him the truth.
9. Relieve his anxiety.
10. Try to like him.

— Martin Gumpert, M.D.

You and Your Doctor, Bobbs-Merrill, 1952

One of Laennec's Cases

In 1816 I was consulted by a young woman who presented general symptoms that pointed to the existence of some disease of the heart, and in whom, by reason of her embonpoint,* simple palpation and percussion could scarcely be expected to furnish satisfactory information in regard to the nature of the disorder. The age and sex of the patient not permitting me to make such an examination as I have just mentioned I was compelled to adopt some other measure; and I then recalled to mind the acoustic phenomenon with which everybody is familiar, to-wit: if the ear be applied to one end of a wooden beam it will perceive with perfect distinctness the sound made by the scratching of a pin's point on the opposite end of the beam. From this circumstance I inferred that in the present case I might advantageously utilize the principle underlying this phenomenon. Accordingly I rolled up into a cylinder-shaped, stiff-walled tube several sheets of writing-paper, and, resting one end of the clinder on the skin of the precordial region, I applied my ear to the other end of the tube. I found to my surprise and pleasure that I was now able to hear the pulsations of the heart much more distinctly than I had ever before heard them when I applied my ear directly to the chest-wall.

— Laennec, Rene (1781-1826)

Unamuno, the Agonist

"I Want to Live"

"I do not want to die — no; I neither want to die nor do I want to want to die; I want to live for ever and ever and ever. I want this "I" to live — this poor "I" that I am and that I feel myself to be here and now, and therefore the problem of the duration of my soul, of my own soul, tortures me."

These anguished words came from the naked soul of the existentialist Spanish philosopher, Miguel de Unamuno, who was obsessed by the irreducible contradiction between faith and reason: the heart's desire for immortality and the mind's awareness that man must die.

Annihilation being inconceivable and immortality undemonstrable, Unamuno had to admit the existence of the dichotomy; but in his agonizing doubt and despair he advocated that man not meekly resign himself to but valiantly fight against the paradox he himself had produced but could never resolve.

This heroic but vain struggle is the theme of Unamuno's two books, "Tragic Sense of Life" and "The Agony of Christianity," both placed on the Papal Index, although, ironically, their author was a Catholic.

Milk Sickness*

MILK SICKNESS was a disease of considerable importance to public health in the pioneer settlements of Tennessee, Ohio, Indiana, Illinois, and Missouri. This disease was described as early as 1776 in North Carolina, but for more than 100 years the cause remained unknown. Today, although this disease is becoming a medical curiosity, it is interesting to speculate on the reasons why the cause of milk sickness, which ravaged so many pioneer families and their livestock, remained obscure for such a long time.

We now know that milk sickness in man and trembles in animals are caused by tremetol, a complex alcohol found in two perennial herbs: white snake root and rayless goldenrod. White snake root is seen in woods of all types and along streams in wooded pastures in the middle west. Rayless goldenrod is found on the dry plains, grasslands, and open woodlands of the southwestern part of the United States.

As pioneer families established farms west of the Allegheny mountains, they first cleared land for crops and gardens, leaving their livestock to browse the adjacent wood-

land. Since wooded areas do not have the grazing potential of cleared areas, livestock were often vulnerable during the summer months to the effects of browsing white snake root plants. Cows giving milk were especially vulnerable because of the demand for additional nutrients necessary in milk production. However, the lactating cow was often able to survive by excreting tremetol into the milk. Thus, as man drank the milk or ate milk products, he became an unsuspecting victim of milk sickness.

These pioneers were seeing a new disease not observed on the eastern seaboard or reported in European medical literature. Not having the knowledge of present-day botanists, these newcomers did not know that only one of more than 40 species of white snake root (*Eupatorium urticaefolium*) was poisonous. If we realize that at the time there were few veterinarians and physicians, that the scientific method was unknown, and that medical communication among the frontier doctors was almost lacking, then we can understand the painfully slow progress on the etiology of milk sickness.

We Wonder!

Why did Nature create man? Was it to show that she is big enough to make mistakes; or was it pure ignorance? — Holbrook Jackson

In peptic ulcer... antacid therapy with a new benefit

CONTAINS A BALANCED
COMBINATION
OF THE MOST WIDELY
USED ANTACIDS—
FOR RAPID
NEUTRALIZATION.
PLUS SIMETHICONE—
TO CONTROL
THE FACTOR WHICH
ANTACIDS ALONE
CANNOT INFLUENCE.

Mylanta[®]

- In Mylanta, aluminum and magnesium hydroxides are balanced to minimize the chance of constipation or laxation and still achieve rapid acid neutralization and pain relief.
- The positive action of simethicone helps relieve the painful gas symptoms which often accompany the peptic ulcer syndrome.
- The nonfatiguing flavor and smooth, nongritty consistency of tablets and liquid encourage continued patient cooperation during long-term therapy.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) of liquid contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. **Dosage:** one or two tablets, well chewed or allowed to dissolve in the mouth, or one or two teaspoonfuls of liquid to be taken between meals and at bedtime.

Cardiopulmonary Resuscitation*

THE MODERN techniques of cardiopulmonary resuscitation are sufficiently easily understood and carried out that they may be successfully employed by teams or individuals who may not be physicians. The article, "Restoration of Cerebral Physiology: An Unusual Case of Cardiac Resuscitation" by Dr. Leroy Ekstrand serves to illustrate the kind of team effort Ekstrand worked to produce. This kind of effort on his part will certainly be a monument to his memory in his community.

There are two stages to cardiopulmonary resuscitation in terms of time. The first is the institution of closed-chest cardiac massage or mouth-to-mouth resuscitation, or both, as soon as a cardiac or a pulmonary emergency occurs. Brain damage can be expected to begin four to six minutes after effective circulation stops. If resuscitation is to have a chance of succeeding, it must be

instituted by people on the scene, without waiting for the arrival of a physician. The second stage consists of electric defibrillation, the use of pressor agents, agents to combat acidosis, cardiac pacemakers, and the many highly technical procedures that require a physician, a hospital, and, hopefully, an intensive care facility. The patient can benefit by the second-stage procedures only if trained persons are ready to treat him in the brief six-minute time limit of the first stage.

Each community can follow the example of Dr. Ekstrand and the firemen he trained. Training exercises using a manikin, films, and demonstrating devices will help to produce teams of competent people. The physicians of the community are in a unique position to act as teachers in this field and extend the possibility of saving lives.

The Diagnosis of Gastric Ulcer*

IN THE MANAGEMENT of gastric lesions, surgery is often employed as a diagnostic method as well as a therapeutic one. If other diagnostic methods were more exact, wiser therapeutic choices could often be made between non-operative medical management and a preplanned surgical approach.

We have generally overburdened the radiologist by the weight of responsibility placed on his techniques and ability, whose accuracy only timely repeated examination or surgery — or autopsy, can verify. This is still relatively true despite the undoubted real improvement in x-ray diagnosis consequent to the use of cineradiography. The results of these techniques used prospectively by well-trained persons are reported elsewhere in this issue and represent the impressive ultimate and extraordinary results of such efforts. They are extraordinary in that techniques employed do not yet represent the usual diagnostic facilities available to

the majority of patients. They are ultimate in that this is a degree of excellence for all to seek. One means of approaching this diagnostic accuracy generally is to make modern radiographic techniques and abilities more generally available, and this is happening. Another is to improve other complementary and validating diagnostic methods. This too, is happening.

Recent technical developments in flexible fiberoptic lighting and viewing systems and in photographic equipment have moved direct intragastric visualization into first line position, importantly complementing x-ray techniques. Our own reasons for this conclusion are based on the experience gained in over 1,000 examinations using primarily the GTF Olympus Fiberoptic Gastroscope Camera.** They are supported by the increasing utilization of these same techniques by other interested persons in this medical community and by the reported experience of others using the same¹ and other fiberoptic

equipment elsewhere.^{2,3} As compared with earlier equipment, procedures using flexible fiberoptic systems are not traumatic or morbid, thus becoming applicable to more patients. Blind areas are consistently reduced. Easily obtained, good quality color film records allow serial comparison and follow-up of a given lesion, removing the variables of imperfect recall by one endoscopist. Also, film comparison with other similar lesions has tremendous teaching value, as does the direct endoscopic "panavision" view of the stomach.

Most importantly, modern gastroscopy is an accurate diagnostic technique. Of 170 proven gastric ulcers evaluated during the past three years at the Minneapolis Veterans Hospital by both x-ray and endoscopic techniques, fiberoptic gastroscopy and photography has been employed in the majority. Only two lesions were not visualized on initial examination with this equipment. All of the 10 malignant ulcers in the series were correctly diagnosed endoscopically. Of the 158 benign ulcers seen, nine were initially called probably malignant gastroscopically, but were proven benign on histologic examination of surgical specimens. Four of these were thought to be malignant by the surgeon examining the lesion grossly.

Evaluation of any diagnostic technique must consider not only the accuracy with which the specific pathologic process is identified, but also the accuracy with which all existing lesions in patients studied are discovered. The latter is difficult in evaluating clinical techniques since not all studied patients come to direct surgical or autopsy comparison. Evaluation of our experience is further hampered by the fact that examinations on very active and busy teaching endoscopy and x-ray services are done by supervised resident trainees in gastroenterology or radiology. The latter do most routine work with conventional x-ray techniques, employing occasional cineradiography. Therefore, our experience cannot be closely compared with that of fully-trained examiners. Nevertheless, it is noteworthy that of the 170 gastric ulcers proven by any means, we missed two benign ulcers endos-

copically, while 58 benign ulcers and four malignant ulcers would have been missed on initial examination had not gastroscopy been performed.

Finally, modern day gastroscopy can so completely examine the stomach, with such good optical resolution that diffuse mucosal abnormalities such as mucosal atrophy or hypertrophy, and notably acute antritis can now be identified and studied further. Gastric pathology has long suffered for the lack of such gross correlates. We are also prospectively studying the means by which fiberoptic gastroscopy and cineradiography may complement each other in the important discovery of sources of acute upper gastrointestinal hemorrhage.

All gastric ulcers should be initially regarded as suspicious for malignancy until all possible characteristics are defined. However, not all gastric ulcers need any longer be immediately removed surgically. If the lesion appears quite definitely benign radiologically and/or endoscopically, it should be determined that on full ulcer regimen progressive healing occurs on serial examination. Follow-up study at least once within three months of apparent healing is advisable. Non-healing in three weeks or incomplete healing in six weeks should make early operation a very serious consideration. "Apparent" healing of malignant ulcers has been noted, though infrequently, and if carefully examined, most of these lesions will have other characteristics which place them in the next group rather early.

This next group includes those lesions whose benignancy is variably questionable on initial study. These should be promptly and thoroughly studied by cineradiography and gastroscopy when available and, depending on the assessment of malignant probability, either operated at once or followed for one or two weeks and re-studied. The latter approach is justified at times because edema around a benign, usually antral, ulcer can be indistinguishable from infiltration with stiffness and loss of peristalsis. On re-examination after even 7-10 days of ulcer management, the appearance may be more

evidently benign and can then be cautiously followed for a short period.

As a general attitude, while diagnostic methods are becoming more accurate and available, we must continue to err on the side of "over-calling" malignancy and to follow gastric ulcers closely, since not even the gross appearance always distinguishes be-

tween benign and malignant ulcer. This is particularly important since early operative management of the malignant ulcer apparently offers a substantially better prognosis than that of all gastric malignancies.

Amebic Liver Abscess

THE ARTICLE by Doctors Farley and Linner in this issue of MINNESOTA MEDICINE* makes it amply clear that no longer can we regard tropical diseases and parasitic infestations as interesting but vague entities of our medical school parasitology course to be forgotten as we go out to practice in the temperate climate of Minnesota. The airplane and the "guided tour" have brought vacations to Mexico, Central America, South America, and even Africa and the Orient within the financial and time budgets of many Americans. By the thousands, Americans (including Minnesotans) are flocking to these areas, endemic for protozoan and parasitic diseases. Those becoming infested, may manifest no symptoms until long after their return home. The unwary Minnesota physician confronted with a bizarre symptomatology may be led completely astray unless the travel history is elicited, and it leads him to search for tropical diseases by the special diagnostic procedures available.

The finding of three cases of amebic hepatic abscess at one community hospital in Minneapolis in a three-year period attests to the fact that this entity is not as rare as many physicians in this area would believe.

The diagnosis of amebiasis is not always easily made. If the stool and proctoscopic examinations are negative, one may have to proceed with treatment on clinical grounds alone. Recently a hemagglutination test has been devised which gives strong supportive evidence when the above examinations are negative. Unfortunately, the test is not generally available and is run only by the Com-

municable Disease Center in Atlanta, Georgia, on blood specimens submitted through the various State Health Departments. In a critically-ill patient, treatment may have to proceed before the diagnosis is confirmed.

Patient 2 in the article by Farley and Linner had a positive hemagglutination test which was not reported until after treatment was completed.

The recent development of the technique of liver scanning with radioactive gold or radioactive rose bengal has added a useful tool for the diagnosis of amebic liver abscesses. Although the scan does not give a definite diagnosis, it does locate a space-occupying lesion within the liver and directs attention to the advisability of surgical drainage; furthermore, it helps guide the probing needle of the surgeon. Surgery on a case of amebic hepatitis without abscess would be inadvisable; but the scan here would be expected to be negative.

Treatment of suspected amebiasis either alone or with hepatic abscess should not be delayed in the seriously-ill patient even if proof of the diagnosis is lacking. On the other hand it should be recognized that anti-amebic therapy, especially emetine, may be toxic. Heart damage may ensue from emetine and may be permanent. Farley and Linner's Patient 2 did develop considerable electrocardiogram change which fortunately was transient. A peroneal nerve palsy did remain as a permanent residual in that case, presumably due to the emetine, but perhaps just a result of his debilitated state.

Photo professionally posed

Mike expects a penicillin injection. He's about to be pleasantly surprised.

His physician is going to prescribe an oral penicillin — **PEN • VEE® K** (potassium phenoxymethyl penicillin). It's usually so rapidly and completely absorbed that therapeutic serum levels are produced in 15 to 30 minutes. Higher serum levels generally last longer than with oral penicillin G.

Indications: Infections due to pathogens susceptible to oral penicillin G. Prophylaxis of rheumatic fever in patients with previous history of the disease.

Precautions: Skin rash, symptoms resembling those of serum sickness, or other manifestations of penicillin-allergy may occur. Measures for treating anaphylaxis should be readily available; epinephrine, oxygen and pressor drugs for relief of immediate allergic reactions; anti-

histamines and corticosteroids for delayed effects. Penicillin may delay or prevent the appearance of primary syphilitic lesions. Patients with gonorrhea who are suspected of concurrent syphilitic infections should be tested serologically for at least 3 months. Where lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. As with other antibiotics overgrowth of nonsusceptible organisms may occur; if so, discontinue and take appropriate measures. Treat β -hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent development of rheumatic fever or glomerulonephritis.

Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity

Composition: Tablets—125 mg. (200,000 units) and 250 mg., (400,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

Wyeth Laboratories Philadelphia, Pa.

(potassium phenoxymethyl penicillin)

Information Systems Technology as an Aid to Medicine

PHYSICIANS, FOR the most part, have not experienced the professional stresses that the advent of automation has thrust upon those working in industry. It is essential for the medical profession to prepare itself for radical changes which it soon must face. These changes are exemplified by Dr. Morris Collen's* pioneer work in California in the utilization of data-processing techniques for providing periodic health check-ups to large numbers of people.

A physician functions in two ways: as data collector and processor and as decision-maker. He collects, abstracts, and records data regarding each patient and then compares this data with prior medical experience to make diagnostic and therapeutic decisions. To provide up-to-date health care for his patients the physician of today faces two enormous problems: the problem of ef-

ficiently collecting and processing data on the individual patient among his rapidly increasing number of patients, and the almost hopeless problem of retrieving rapidly for medical decision-making pertinent data from a medical literature which, it is estimated, is doubling in quantity every 10 years. The new technology of electronic data processing and its extension into control of automated machines promises enormous aid toward the solution of these problems. However, it may be that solutions can be achieved only by accepting radical changes from the traditional methods of thinking and acting in current medical practice. Education and preparation for extensive change are essential, if we are not, collectively as a profession as well as individually as members of a changing society, to find ourselves disorganized and unable to cope rationally with a new professional environment.

Boustrophedonic Scanning of the Lung

BOUSTROPHEDONIC* SCANNING of the lung following the injection of radionuclide-labeled macroaggregated albumin has proved to be a powerful new tool in the assessment of pulmonary function.

From the original brilliant idea of Bénacerraf and associates¹ in France, colloidal material was developed as a lung-scanning agent in this country, largely by Taplin and associates.² Numerous other reports have subsequently appeared in the literature.

This method was developed originally for the detection of pulmonary emboli, but although it performs this task quite well, this has proved to be one of its less important uses; it seems to be a much more widely applicable tool.

When injected into the peripheral vein, the macroaggregated albumin seems to follow the path of the venous blood from that vein and to lodge for a period of an hour or so in the first capillary bed it encounters,

normally in the lung. Since usually it is cleared almost completely by the lung, it affords an excellent index of pulmonary blood flow. Indeed, early evidence now indicates that when digital computing devices are applied to scan data, quantitative information may be obtained.³ In the presence of a right-to-left shunt, total count rates over the lungs apparently decrease by approximately the degree of the shunt.

The lung scan has been of great value in indicating the distribution of blood within the lung, including the striking effects of gravity on pulmonary flow. Scans from patients injected in a feet-down position show that the blood flow is predominantly basal and that almost no flow from the right ventricle reaches the apex, which supports the old theory of the apical distribution of pulmonary tuberculosis. After injection in a feet-up position, the flow is predominantly apical. This varying distribution is most striking in subjects who have large lungs, in

"All Otolaryngologists are Alike"

Just look at them and you can see how much they have in common. Besides, they all go through pretty much the same training, and pass the same kinds of tests, and measure up to the same sort of standards. Therefore, all otolaryngologists are alike. Right?

Wrong! But that's no more preposterous than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more exacting. In fact, there are at least nine *specific differences* involving moisture content, purity, potency and speed of tablet disintegra-

tion, which make the manufacture of Bayer® Aspirin so different.

These Bayer standards result in significant product benefits, including gentleness to the stomach and product stability, that enable Bayer Aspirin tablets to stay strong and gentle until they are taken.

So next time you hear someone say that *all* aspirin tablets are alike, you can say, with confidence, that "it just isn't so."

You might also say that all otolaryngologists aren't alike, either.

which dependent filling is a constant finding.

In patients with increased left mean atrial pressure, pulmonary flow is predominantly apical, and this finding supports the old theory of Virchow which explains why patients with mitral stenosis have a low incidence of tuberculosis. Computerized scans may afford a good index of left mean atrial pressure.

One of the most striking aspects of pulmonary scans is that they are so often positive and correlate with pathologic processes in the face of negative roentgenograms of the chest.⁴

*Mayo Clinic and Mayo Foundation.

References may be obtained from the author.

Chest roentgenograms give basically architectural information; lung scans provide basically functional information specifically relating to pulmonary blood flow. Other facets of this diagnostic technique currently under consideration are inhalation scans and scans following injection of gamma ray-emitting gases (xenon-133).

The pulmonary scan seems to be extremely safe, is easy to perform from the patient's standpoint, and provides a great deal of information. It is likely to prove a diagnostic tool that will last.

Stapedectomy

RENEWAL OF A forgotten procedure with the advent of the surgical microscope and associated tools and techniques has placed the availability of near normal hearing to many who suffer from a particular type of conductive hearing loss; i.e., that due to fixation of the stapes. Despite the fact that little is known of the etiology of the diseases that produce fixation of the stapes, correction in the majority of patients achieves results that can hardly be matched by many surgical procedures.

It requires the patient to lie quietly for one to two hours with the head turned to the side. A local anesthetic is injected into the ear canal. The operative field is confined to the ear canal and middle ear. Exposure is obtained by elevating a flap of canal skin and the attached ear drum forward. The stapes is either removed or remodeled and the ossicular chain is reconstructed with a variety of techniques, most of which give good hearing results.

Complications occur rarely. Vertigo is common in the immediate postoperative period but usually subsides in a few days. The most serious complication is complete loss of hearing in the operated ear. This fortunately occurs rarely. The various complications as enumerated by Barnett Eades*

in the November issue of MINNESOTA MEDICINE should be foremost in the mind of the surgeon in evaluating candidates for surgery but should not deter the family physician in recommending an otological examination for the possibility of surgical correction of hearing loss.

Not all patients with hearing loss will benefit from stapedectomy. Those patients who have a gradual progressive hearing loss that begins between adolescence and early adult life may have otosclerosis. It is familial and occurs more frequently in women than in men. These patients hear better in noise than in quiet surroundings because of the increase in volume of the speaker's voice. Air and bone conduction audiometry and tuning fork tests confirm the diagnosis.

Those patients who have fixation of the stapes at birth from congenital causes may not be diagnosed as hard-of-hearing patients until they are several years old, and the time of onset and therefore the type of pathology present may be obscure. Whatever the cause of the stapes fixation, whether congenital, otosclerotic, or associated with other bone defects such as osteogenesis imperfecta, the treatment is stapedectomy, fenestration of the oval window, and insertion of a prosthesis. The optimum time of surgery, however, may vary in the different

types of pathology. Those patients who cannot understand speech even with volume or who are confused by several people speaking will probably not benefit from stapedectomy because they probably have a sensori-neural problem. This is ascertained by testing the patient's ability to understand speech.

Attempts at restoration of hearing were successful by mobilization of the stapes prior to 1900 but were discontinued. One can speculate that lack of magnification, lack of proper illumination, and unavailability of antibiotics produced complications that outweighed the advantages of surgery. Continued interest in restoration of hearing by surgical means produced the fenestration operation which was refined by Lempert. This was a meticulous and tedious operation that improved hearing but could not restore it to the normal level. However, Rosen rediscovered stapes mobilization inadvertently, and the hearing gain that ensued was so much better than the results from fenestra-

tion, and the procedure itself was so much simpler, that this became the acceptable procedure for restoration of hearing in cases of clinical otosclerosis. It became apparent, however, that many of these mobilized stapes could refix and the hearing loss could again return. Shea proved that the stapes could be removed completely and the ossicular chain reconstituted with artificial material. This produced a more permanent hearing gain. Variations of this technique with either partial or total stapedectomy with insertion of various types of prostheses is the standard operation today for clinical otosclerosis.

Microsurgical techniques are truly modern advances in medicine. They have been refined to the point where further advances in this direction are not likely. Further investigative efforts directed toward etiology of otosclerosis will undoubtedly prevent not only the conductive component but the cochlear (sensori-neural) component as well.

Soyalac

SOLVES THE
PROBLEM

for the infant
who requires a
milk-free diet!

- Soyalac satisfies! Baby is happy, mother is grateful, doctor is gratified.
- The nut-like taste is pleasing. Infants readily accept this hypoallergenic formula that is completely fibre-free. An exclusive process results in a consistency much like milk.
- Soyalac is strikingly similar to mother's milk in composition and ease of assimilation. Clinical data furnish evidence of Soyalac's value in promoting normal growth and development.
- Excellent for regular infant feeding, too—and for growing children and adults.

The Editor's Soliloquy

Don't Rest Yourself to Death

There is no such thing as overwork. A man may die with his boots on: he may die while at work from systemic disease or an accident — but not from work per se. Work of any kind, whether physical or mental, white-collar or blue-collar, can cause fatigue or even exhaustion; but it does not cause death. For with fatigue comes sleep and with sleep comes revitalization, preparing the individual for another day's work in man's diurnal pattern of alternating labor and rest.

Some individuals almost boast of working themselves nearly to death; they comprise a brotherhood of the chronically tired. Such a poor mortal is always insisting that he needs more rest. He requires a nap after breakfast, a mid-morning coffee break, a noon siesta, and an afternoon cigaret break. After work and before dinner he feels the urge for a brief snooze or a relaxing cocktail. He has had such a hard day! Ergo, he needs more rest; and the more he gets, the more he wants. Deciding finally that something must be wrong, he consults a doctor who, not having analyzed his patient's faulty rest habits, pronounces him sound. The very idea! So the vicious spiral continues.

Experimental studies have conclusively shown that in complete rest the body readily goes into a negative nitrogen balance, losing more nitrogen than it consumes, and that as the loss continues atrophy develops — despite a possible gain in weight. Physicians have long since discovered the tremendous healing value of early ambulation in the treatment of most diseases; and it has been repeatedly demonstrated that physical activity is one of the best physiotherapeutic agents available.

So let's liberate ourselves from that pernicious obsession that we are working ourselves to death and can't get rested up. Let's energize ourselves with constructive activities and attitudes so that at the end of the day healthy fatigue will induce natural and re-energizing sleep.

Let's repolarize our negative into positive physiologic and emotional values before we die of ennui and inanition by resting ourselves to death.

Carl O. Rice, M.D.

Vigorous writing is concise; A sentence should contain no unnecessary parts, a paragraph no unnecessary sentences. For the same reason that a drawing should have no unnecessary lines and a machine no unnecessary parts. This requires not that the writer make his sentences short, or that he avoid all detail and treat his subjects only in outline, but that every word tell.

William Strunk Jr., *Elements of Style*

Our Senior Educators

James R. Dawson, Jr., M.D.

WHILE THE OVERALL summation of the prolonged, complex and very substantial contributions of an academician is a difficult achievement for his own generation, the manner in which these contributions are made is readily apparent during his lifetime. There are few men who have moved through their tenure as departmental chairmen at the University of Minnesota Medical School with the modesty and thoughtfulness of Dr. James Robertson Dawson, Jr. In an era of increasing size and complexity of the Medical School and its component parts, Dr. Dawson has made a determined effort to maintain the integrity of the individual and to produce a harmonious department in which the maximum potential of his residents and staff would be manifested. To this purpose a great portion of his energy has been spent in encouraging and facilitating the academic pursuits of both his junior and his senior colleagues, often at a considerable sacrifice to his own personal endeavors.

The philosophical background which served to distinguish Dr. Dawson was instilled in him almost from the time of his birth in Birmingham, Alabama, on January 19, 1908. He was born into a family which had a proud medical lineage extending back for three generations. From

Continued

this heritage was bred a great security in the role of physician and likewise the sense of carrying forward an established tradition. His ancestral background also provided him with an extraordinary sense of ease, graciousness and good breeding which he retained in spite of his transplantation to the comparatively arctic northwest.

Dr. Dawson spent many years of his academic life at Vanderbilt University, receiving a Bachelor of Arts degree in 1928 and a Doctor of Medicine degree in 1931. He then became an Instructor in the Department of Pathology at Vanderbilt University Medical School, where he remained until 1934. A figure who stimulated him greatly was Dr. Ernest William Goodpasture, a pathologist of extraordinary ability, with whom Dr. Dawson had a prolonged and very close relationship. During this early portion of his medical career Dr. Dawson devoted much of his research effort to virology and particularly to viruses affecting the central nervous system. In 1934 he left Vanderbilt to become an Assistant in Pathology and Bacteriology at the Rockefeller Institute for Medical Research, where he continued his work in virology and worked very intensively with the rabies virus. Following a year at the Rockefeller Institute, he became an Instructor of Bacteriology and Immunology at the Cornell University School of Medicine, where he stayed until 1938, at which time he returned to Vanderbilt University School of Medicine as an Associate Professor of Pathology and subsequently became a full Professor in this department.

In 1949 Dr. Dawson came to the University of Minnesota School of Medicine as Professor and Head of the Department of Pathology. This represented both a great honor and a great challenge, since he was assuming the chair of Dr. E. T. Bell, one of the most outstanding medical figures in the history of the Medical School as well as in the field of pathology. Under Dr. Dawson's chairmanship the traditions of an excellent department were maintained and innovations introduced without disruptive effects. A feature which was to be constantly present during his tenure was immediately manifested, namely the effort to integrate the department in such a manner as to provide an opportunity for each member to devote the most time possible to those areas in which he showed the greatest interest and productivity. Thus from the beginning there was a department which worked harmoniously and with a feeling of maximum support from its department head.

Dr. Dawson has a commitment to the concept that the chairman of a department should devote himself to the academic advancement of individuals at all levels at which the department functions. Thus he has presented the majority of the lectures to the medical students; and with the residents he has devoted a great deal of time to reviewing their autopsy material. Since a solid experience in autopsy pathology is essential for the mastery of pathology, this has provided a fundamental training few other institutions offer. He likewise has made himself available for consultation and advice to his departmental colleagues. This has been done in an unhurried spirit of mutual exploration and with great wisdom and objectivity, so that the final result has reflected a combined effort in which Dr. Dawson's very profound intellectual capacities and extensive knowledge of medicine and pathology have made an important contribution. Thus, during a period of rapid growth of medical techniques and

facilities with all of the potential for turbulence and distortion, there has evolved under Dr. Dawson a department sturdily grounded in fundamentals, working cohesively and effectively, a department in which all the members have been fully aware of the depth of strength, wisdom and encouragement which their chairman has imparted.

Lee W. Wattenberg, M.D.
Minneapolis, Minnesota

Medical Men on Postage Stamps

Paul Ehrlich (1854-1915), German bacteriologist and 1908 Nobel Prize winner, was medicine's pioneer in chemotherapy: the application of chemistry to disease. He discovered the "vital stain" theory and is credited with a cure for syphilis — salvarsan or "606." For his achievements in the field of immunology along with those of his colleague, *Emil von Behring* (1854-1917), German bacteriologist and 1901 Nobel Prize winner, Germany issued a commemorative postage stamp in 1954.

Carlo Forlanini (1847-1918) was an Italian surgeon whose renown rests on his performance of the first pneumothorax operation (1892). In his memory Belgium honored him on a postage stamp issued in 1953.

It may be interesting to turn back the pages of history a few hundred years, to see what some of the really old boys had to study and stomach. Blasius Gronewalt began his medical schooling at the University of Leipzig in 1506 and in later years the books that he had used were collected by the library of Kreuzschule at Leipzig. There were only two medical books in the collection. One was the tractates and expositions of Petrus Hispanicus, who was a practising physician during the late thirteenth century, having studied at Montpellier and Paris. This book concerned treatment and dietetics and was based a great deal upon the sayings and teachings of Hippocrates (460-370 B.C.) and Galen (130-200 A.D.). The other medical book was the "Pandectae Medicinae" by Matthaeus Sylvaticus, which was a reference text of pathology and pharmacology. All of the other books were of a nonmedical nature and included texts on metaphysics, astrology, politics, ethics, economics, famous editions of Aristotle and the works of Cicero, Caesar, Plutarch, Valerius Maximus, Ovid, Livy, and Quintilian. In addition, the poor fellow had to study Greek!

— F. William Saul, M.D.: Pink Pills for Pale People

He who does not know how to manage properly a case of irritability of the stomach will never be able to treat successfully any other malady. In short, the key to a knowledge of pathology is to be found in an intimate acquaintance with gastritis and gastroenteritis.

— Francois Broussais (1772-1835)

BE A MYTH- MONGER #5

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

APACHE PLAZA MEDICAL COMPLEX IS DEVOID OF ALLIED MEDICAL SERVICES

Other than pathology lab, radiology lab, professional pharmacy and ancillary services. That is to say, if you require facilities for major surgery, forget Apache Plaza Medical Complex. But if you can utilize the afore-mentioned allied services, together with offices designed to *your* specifications in the fastest growing area in the Twin Cities, give us a ring.

Curbstone Consultation

Cockroaches

QUESTION: Cockroaches, no doubt, are present throughout the world. In some areas they seem more numerous than others. (1) Are cockroaches carriers of disease? (2) Briefly, what is the best method of controlling cockroaches?

ANSWER: To the best of my knowledge, cockroaches have never been directly implicated as carriers of diseases of man. It is postulated that they could mechanically carry pathogenic bacteria in their wanderings from areas contaminated by sewage, perhaps much in the same way that flies do. However, because of their habits, they are less likely to do this than flies and, in any case, I don't know that they have ever been implicated as carriers of infectious disease. To the best of my knowledge, they do not in any other way act as direct vectors or as intermediate hosts for diseases in man.

With respect to control, the problem presents certain difficulties. As you know, cockroaches are very easily brought into the household in food packages and quickly get themselves established. They like the moist, dark places and establish their habitats in such areas. They are largely nocturnal in their habits. They usually establish themselves in areas where they have access to food. A large part of the problem in controlling them is that they drop their egg capsules in inaccessible places and these capsules often take many months to hatch. Therefore, any program of eradication would have to continue for at least six months or more. The best treatment is prevention with good sanitation and house-keeping.

The most widely used control agent, and probably the most effective one, is chlordane. This is used as a residual pesticide around baseboards and other areas where the roaches have established their runs. Spray materials are also used for their control, and of these malathion and diaznon, with or without pyrethrins, are the most effective. In years gone by, fumigation was sometimes used, but I believe that this type of treatment has been largely abandoned. Commercial establishments often engage professional pest control operators to handle the problem for them. These people will come in at regular periodic intervals to treat the infested areas.

The Viewing Box

The Wheezing Child

A 17-month-old girl was admitted to Childrens Hospital because of wheezing and coughing. The past medical history was negative. On physical examination an audible wheeze was present but the infant was not in acute distress. Bilateral wheezing rhonchi, more pronounced on the left, were present. The breath sounds were diminished on the left, but there was no retraction.

Inspiration

Expiration

What is your diagnosis? (See next page.)

DIAGNOSIS: Foreign Body in the Left Main Stem Bronchus

In the above case further history revealed that the child had stumbled shortly after the mother had placed half of a shelled peanut in its mouth, and immediately developed acute wheezing and coughing. At bronchoscopy, half of a peanut was removed from the left main stem bronchus.

The most frequent cause of bronchial obstruction is bronchial inflammatory disease with partial or complete obstruction of the bronchus due to inflammatory exudate or mucus plug. Bronchial foreign bodies are a more spectacular but a less common cause of bronchial obstruction. Any child who develops a wheeze or cough after having an object in the mouth must be considered to be harboring a foreign body until proven otherwise.

A negative history regarding foreign body ingestion does not rule out this possibility in infants and children, since history is notoriously misleading in this age group.

This is a case of obstructive emphysema in which the foreign body acted as a check-valve in the left main stem bronchus allowing ingress of the inspired air but occluded the bronchus during expiration and produced obstructive emphysema.

The importance of both inspiratory and expiratory chest films is well illustrated by this case. With only a routine inspiratory film, the foreign body would have been missed. However, the expiratory film clearly revealed obstructive emphysema on the left and contralateral mediastinal shift.

Ancient Childrens Hospital Proverb: In child with wheeze, take two films (insp. and exp.) please.²

Uroscopy

From time immemorial the urine has been naturally the subject of medical interest. As practiced in the 17th century it was known as Uroscopy, or "water casting." The urine, usually in a flask, was brought to the physician, who held it to the light with solemn and judicial air, while he read the patient's fate in the uplifted urinal.

"Red Urine signifieth heat of the blood; white, rawness and indigestion in the Stomach; thick, like puddle, excessive labor or sickness; white or red gravel in the bottom threatens the Stone in the Reins; black or green, commonly death."*

Fracture-Trauma Conference

Motorcycle Injuries

An Analysis of 287 Victims — A Three-Year Study

IN THE LAST three years, from 1964 to 1966, a continuing study* has been conducted as to the number of injuries from motorcycle accidents seen at Methodist Hospital, Minneapolis, Minnesota, covering the five-month season — May to September. The initial results of the study were published in 1964 entitled "Motorcycle Injuries — An Increasing Traffic Problem" in MINNESOTA MEDICINE, April 1965, Gustilo et al. The study included cases that were seen at Hennepin County General Hospital.

A total of 287 victims were seen at Methodist Hospital emergency room during this three-year period. There was an increase of 23 per cent in accident victims seen in 1966 compared to 1964. Males were involved about five times more than females. The age distribution is presented in Table 1.

TABLE I

I.	Under 1	1
II.	1 to 10	6
III.	11 to 15	42
IV.	16 to 20	156
V.	21 to 25	38
VI.	26 to 30	17
VII.	Over 30	15

Of interest is the alarming number of accident victims 15 years of age or less shown in this table.

Motorcycle injuries involve primarily the extremities, resulting in fractures or ligament strains of various degrees (mild, moderate, and complete). The femur and tibia are the most frequently involved in either closed or open fracture types with occasional vascular and nerve injuries. Injuries to the brain and skull are usually fatal. The use of the helmet, however, precludes or diminishes such injuries. Therefore, the helmet is the most important single piece of equipment for a motorcycle driver. In the study of 200 patients with motorcycle injuries in 1964 at Hennepin County General Hospital and Methodist Hospital, Minneapolis, two deaths were reported, both from skull and brain injuries. Neither of the drivers wore a helmet.

*This study was supported through the St. Louis Park Medical Center Research Foundation, Minneapolis.

Continued

In the present study of 287 patients there were 26 serious head injuries. There were three deaths resulting from head injuries and helmets were not used by the victims. About 75 per cent of minor injuries are preventable, and at least 50 per cent could have been prevented with proper clothes and/or equipment.

The injuries are classified as minor or major. There were 72 major injuries and 215 minor injuries in this study. Minor trauma included simple lacerations, sprains and contusions which did not require hospitalization and which could be easily treated in the emergency room. The major category included fractures (simple, multiple, closed, and open), traumatic amputation, large lacerations, cerebral and skull injuries, and intra-abdominal injuries which necessitated either hospitalization or immediate surgical intervention. Ninety per cent of the major injuries involved the lower extremities, consisting of single or multiple fractures of the tibia, femur or pelvis.

The major injuries sustained by 72 patients are of the following types (Table 2).

TABLE 2
Types of Injuries

I. Closed fractures — 28 patients
II. Open fractures — 6 patients
III. Head injuries — 26 patients
A. Deaths — 3
IV. Chest injuries — 4
V. Spine injury — 1
VI. Miscellaneous — 19

The exact nature of these accidents can be classified into two general categories (Table 3). 1. Motorcycle upsets. 2. Motorcycle collisions.

TABLE 3
Nature of Accidents

I. Car-motorcycle collisions — 63 cases or 22%
A. Collision with turning car.
B. Head-on collision with car.
C. Collision from rear by car.
II. Upsets from various causes — 224 cases or 78%
A. Skidded on road because of no gravel.
B. Fell off for no apparent reason.
C. Lost control and turned over.
D. Accelerated too fast.
E. Collided with another motorcycle.
F. Unable to locate brake.
G. Caught fingers or feet on chains or spokes of wheels.
H. Hit immobile object fast.
I. Front wheel slipped.

The lower extremities were frequently involved with a ratio of 2:1 compared to upper extremities.

Discussion

The increasing popularity of the motorcycle both in sports riding and as a mode of transportation involves millions of Americans both young and old. It will continue to flourish and to occupy its proper place on public roads and open highways. The alarming number of victims and the severity of injuries demand public scrutiny and concern.

MOTORCYCLE INJURIES

The most common cause of accidents is improper and inadequate training of motorcycle drivers. The fact that one has a car license is not a good criterion and justification for driving a motorcycle. This light-weight machine is a potentially dangerous vehicle traveling at a very high speed. A car-motorcycle collision is the number one cause of serious injuries — commonly due to the fact that the car hits the motorcycle on the blind side in turning either left or right. Motorcycles should occupy the road just like a car and follow the rules and regulations that car drivers are required to follow.

The use of a helmet should be an absolute requirement for all motorcycle drivers.

It was alarming to note that a large number of accident victims were under 15 years of age, the majority of them passengers. A motorcycle is designed as a one-man vehicle and an additional passenger constitutes a real hazard. There are enough inherent hazards in motorcycle driving without the presence of a passenger hugging the driver.

A metropolitan-wide comprehensive study of this problem is urgently needed, particularly with regard to the licensing of motorcycle drivers and the frequency of motorcycle accidents.

Mr. Barzun Comments

Obesity

Passing from form to substance, it would seem as if our national well-being could be enhanced by a better distribution of medical efforts. Cancer is a dreadful scourge, but it seems at the moment to be nearly monopolizing talent and resources. Is the reason for this wholly disinterested and practical? Why not balance the research with a systematic review of the effects of what we take into our bodies, together with a study of our actual habits? We might learn to forestall some of our ailments as well as some of the drags on our living powers, notably that of obesity, which is a national curse. Though we live longer we do not age gracefully. Modern occupations, which are sedentary, only partly account for this: we sit and thicken, true, but that is not all there is to it. Since all foods "fatten," we must for some reason other than greed overeat. The obsession of women after thirty, of men after forty, with diets, reducers, and other means of averting the apparently inevitable cannot be called either mistaken or healthy. It seems absurd to talk of our control of nature when all we can do is use rubber bands to keep our women's shapes within bounds.

Tumor Conference

Rupture of Bronchus

A 19-year-old Caucasian male was involved in an automobile accident. The machine he was driving left the road, striking a culvert. The patient was noted to be unconscious and in a moribund condition. Shortly thereafter he was brought by ambulance to an emergency room where a physician performed a tracheotomy. After the tracheotomy, much bloody mucus was aspirated. The patient's condition improved sufficiently to allow him to be transported to a larger hospital.

A pneumothorax was demonstrated here on a PA roentgenogram of the chest (Figure 1). An intercostal catheter was positioned and placed to suction. A vigorous air leak was noted immediately and continued for several days. Failure of closed suction prompted thoracotomy six days after injury.

At thoracotomy, a pulmonary laceration was found, and suture of the laceration was effective in controlling the air leak. The postoperative course was uneventful, and the patient left the hospital on the fifth postoperative day. An x-ray of the chest eleven days postoperatively was normal.

Fifteen days postoperatively and 26 days following the injury, the patient returned extremely short of breath. A roentgen examination of the chest at this time (Figure 2) revealed complete opacification of the right hemithorax. Bronchoscopy showed obstruction of the right main stem bronchus by what appeared to be granulation tissue. A bronchogram (Figure 3) revealed complete obstruction of the right main stem bronchus.

Figure 1

Figure 2

Continued

Figure 3

A second thoracotomy was performed 26 days after the injury, and detailed dissection of the pulmonary hilum was carried out. A bronchial laceration with incomplete separation of the cut ends of the bronchus was found. This was repaired by resection of the fibrotic ends and re-anastomosis using 3-0 chromic sutures. The postoperative course was uneventful. Postoperative roentgenograms of the chest and a bronchogram revealed satisfactory reconstruction and healing (Figure 4). The patient remains asymptomatic.

Figure 4

Discussion

Bronchial rupture or injury must be suspected in all serious thoracic trauma. Unexplained persistence of pneumothorax, despite intercostal suction, coupled with expectoration of bloody mucus, is a clue which should alert the examiner to the possibility of a bronchial rupture. Air passage in and out of the involved lung can occur for a period of weeks after the injury, provided the tear is incomplete. Persistent atelectasis or pneumonia is an additional clue suggesting a diagnosis of injured bronchus.

Recent surgical advances in the field of lung transplantation and extensive bronchial resections for malignancy have yielded valuable experience in the field of bronchial reconstructive surgery. Excellent results can be expected if the diagnosis of bronchial rupture is made. Post-operative pulmonary studies demonstrate satisfactory function of the reconstructed segments.

Petrus Hispanus

In his Commentaries Petrus Hispanus (c. 1215-1277), self-styled "professor of the art of medicine and investigator of the truth," revealed his empirical bent by posing such provocative questions as:

Can natural death be retarded?

How can animals who eat poisons be food for men?

Why is man less hairy and of weaker constitution than the brutes?

Why are animals soft in infancy and fruits hard?

Should paralytics eat fried fish?

Why is oil best at the top, honey at the bottom, wine in the middle of the cask?

What part of water is more truly water: top, bottom, or middle?

Why are pigs' intestines the best of animals that walk and geese's intestines of those that fly?

Is human milk subtler than asses' milk?

If the spleen causes laughter by purifying the blood, why isn't love caused by the gall-bladder?

Is raw cheese better than cooked, and solid cheese or cheese with holes in it?

Why are fools so fond of cheese?

Why does human urine enrich vines?

Are apples good in fevers?

Why pepper is good for dimmed eyes?

Remedies Derived from Living Creatures Remedies Derived from the Elephant

The blood of the elephant, the male in particular, arrests all those defluxions known by the name of "rheumatismi." By the touch of an elephant's trunk, head-ache is alleviated, if the animal happens to sneeze at the time more particularly. The right side of the trunk, attached to the body with red earth of Lemnos, acts powerfully as an aphrodisiac. Elephant's blood is good for consumption, and the liver for epilepsy.

Mushroom Poisoning (Mycetismus)

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

FOR CENTURIES the mushroom has served both as a source of food and as a source of psychic stimulation for religious and tribal orgies. Ancient Babylonians and early Romans considered the mushroom a delicacy and on many occasions, historians tell us, mushroom poisoning took its toll. The earliest record of such poisoning was in the fifth century B.C., when it was reported that the wife and three children of the Greek poet Euripides died from mushroom poisoning.¹ The historian Pliny has referred to these early years as "The Golden Age of Poisoning" largely because of the effects of the mushroom.²

The first fatality reported in the United States was in 1871.³ Since that time few deaths from mushroom poisoning have occurred in this country, the latest figures showing 36 fatalities from 1924 to 1965.⁴ Deaths from mushroom poisoning account for less than 2% of all fatalities recorded from poison control centers throughout the country.⁵ At the Mayo Clinic no deaths from mushroom poisoning or reports of patients made seriously ill from the mushroom are on record. A similar situation exists for Minnesota, according to Dr. Warren Lawson, Supervisor of the State of Minnesota Poison Information Center.⁶ Paradoxically, the rarity of mushroom poisoning in the United States seems to be one of its dangerous features, as both its symptomatology and the treatment of its effects are easily forgotten. In contrast, however, the problem in Europe is a major one, the difference probably being due to the more avid mushroom hunters in European countries. In

Germany alone, for example, it is estimated that 200 people die each year from mushroom poisoning.⁴

More than 3,000 different types of mushrooms are known, and of these, 70 to 80 are known to be toxic to man. Apparently there is great variability in individual susceptibility to mushroom poisoning, and there seems to be a similar variability in toxicity among the mushrooms themselves. Some are toxic only if eaten in large quantities, at specific stages of maturity or during certain seasons, or if eaten in the cooked or raw form. Most authors agree that most deaths (90%) are caused by the genus *Amanita* and in particular the *Amanita phalloides*.² Only toxins of the *A. phalloides* or its phenotypes* produce parenchymatous necrosis in man. A large part of the remaining toxic mushrooms probably could be more accurately described as indigestible, as they produce only transient, unpleasant gastrointestinal effects. Buck⁷ has reviewed the 24 fatal cases of mushroom poisoning reported in the American literature as of 1961 and noted the following etiologic agents: *A. phalloides* and *A. verna* (11 cases); *A. pantherina* (1 case); *Gyromitra esculenta* (7 cases); and undetermined species (5 cases).

Amanita Muscaria (Fly Agaric)

This is one of the largest and most colorful mushroom. At times it reaches heights of 12 inches, with caps six to 10 inches in diameter, the color of the cap varying from orange to yellow to white, with the reddish shades predominating. The color, however,

*See Test Your Word Score Page 521.

Continued

changes with the environment and age of the plant and seems to fade in direct sunlight, in rain, or with aging⁸ (Figure 1). This mushroom is commonly called the fly agaric, actually receiving its name from the common house fly, *Musca domestica*, to which it is extremely toxic. *A. muscaria* is found east of the Great Plains, particularly in the upper lake states under the pine and aspen trees and in the Pacific Northwest in forested areas. Closely related to *A. muscaria* is the mushroom *A. pantherina*, which is most frequently involved in muscarinic poisoning in the Pacific Northwest.

Although rarely causing fatalities, *A. muscaria* produces toxic symptoms, which are due either to mass stimulation of the postganglionic parasympathetic fibers or to stimulation of the central nervous system. In addition, symptoms suggestive of atropine toxicity have been noted. Thus, symptoms of intoxication are threefold and depend essentially on the relative amounts of the

three recognized toxic substances present.⁹ The amounts of these substances vary from mushroom to mushroom and even vary within the same mushroom from season to season.

Muscarine

This was one of the first cholinergic drugs to be systematically studied and was first separated in a rather impure form in 1868 by Schmiedeberg and Koppe.¹⁰ It is a quaternary amine, with structural and physiologic similarities to acetylcholine. Muscarine stimulates the postganglionic parasympathetic fiber in a manner similar to that of acetylcholine. In very large doses, muscarine also may stimulate the autonomic ganglia; but these effects are far overshadowed by its effects on glandular tissue and smooth muscle. No effect on skeletal muscle has been noted. Muscarine is 143 times more potent than acetylcholine although the onset of action is much slower. The increased potency of muscarine is most likely due to its resistance to breakdown by cholinesterases. Muscarine is heat stable and hence not appreciably altered by boiling. Its effects are rapidly counteracted by atropine.

Pilzatropin (Mushroom Atropine)

Soon after the isolation of muscarine it was found that an incompletely purified preparation of *A. muscaria* from the Bavarian Alps caused cardio-acceleration, a change inconsistent with the usual muscarine effects. This "impurity" was named pilzatropin by Kobert in 1891, and its chemical structure and paper chromatographic pattern were found similar to those of L-hyoscyamine, a racemic form of atropine.⁷

Pilztoxin

Although not definitively identified, a third toxin called pilztoxin is believed to exist in *A. muscaria*.⁷ Its presence is suggested because of certain manifestations of the central nervous system that persist in both man and animal after neutralization of muscarine. These manifestations are narcotic-like intoxication, convulsions, hallucina-

Fig. 1 — *Amanita muscaria*. (Reproduced with permission from Smith, A. H.: The Mushroom Hunter's Field Guide. Ann Arbor, University of Michigan Press, 1963, 264 pp.)

tions, and occasionally death.

Amanita Phalloides (Death Cap)

A. phalloides and its phenotype *A. verna* are extremely toxic mushrooms found commonly throughout the north temperate zones in America and Europe. Enough poison is contained in a piece of one mushroom to be fatal to man (Figure 2).¹¹

Experimental work on the *A. phalloides* toxin began in 1793 when Paulet discovered that the toxic element was not destroyed by drying or by heat. The toxin itself was first isolated in 1937 by Lynen and Wieland and was called phalloidin.¹² Subsequent to this, four other toxic fractions have been separated, and these may be conveniently classified as phalloin, alpha amanitine, beta amanitine, and gamma amanitine.¹³ Each toxin seems to be a cyclic, sulfur-containing peptide that depends on the integrity of the sulfur atom for its toxic effects. The alpha-amanitine fraction is largely responsible for the toxic effects of the mushroom. Apparently, the toxins are quickly bound to albumin and then "fixed" to the parenchymal cells, thus leading to the necrosis of these cells. Necrosis is particularly evident in the liver, kidney, and brain.

Classification of Mushroom Poisoning

The first and probably still the best classification of mushroom poisoning was set forth in 1923 by Ford,¹⁴ who divided mushroom poisoning into five groups, the division being made according to the predominant clinical features: (1) mycetismus gastrointestinalis, (2) mycetismus sanguinarius, (3) mycetismus nervosus, (4) mycetismus cholericiformis, and (5) mycetismus cerebralis.

Mycetismus Gastrointestinalis

This is a mild illness predominantly of nausea, vomiting, mild abdominal discomfort, and diarrhea. It may be so mild as to occur without note, or at times it may be moderately severe and require medical attention. Symptoms of central nervous system dysfunction are not present, and likewise parasympathetic symptoms in organs other than the gastrointestinal tract are not prominent.

This illness usually terminates spontaneously, and the patient is restored to good health in one or two days. Various mushrooms have been implicated in this type of poisoning, but no fatalities have been reported.

Mycetismus Sanguinarius

This is a relatively rare illness brought on by the eating of *Helvella esculenta* or beefsteak morel, a mushroom found in the upper Great Lakes region; this type of mushroom is toxic to some persons but not to others. Its toxicity is mediated by helvellic acid, a heat-resistant hemolytic poison. Gastrointestinal symptoms are present at the onset and are followed by rapid hemolysis associated with transient hemoglobinuria and mild jaundice. The prognosis is good although fatalities have occurred. Autopsies show widespread pigmentation of liver, kidney, and spleen secondary to the hemolysis.

Fig. 2 — *Amanita phalloides*. Note convex cap with grayish brown center. (Reproduced with permission from Christensen, C. M.: Common Edible Mushrooms. Minneapolis, University of Minnesota Press, 1943, 124 pp.)

Continued

Mycetismus Nervosus (Rapid Type)

This is the poisoning caused by *A. muscaria*, *A. pantherina*, and other less common fungi such as *Clitocybe sudorifica*, *Inocybe infida*, and *A. crenulata*. Symptoms are due to the massive postganglionic, parasympathetic stimulation by muscarine. They begin from a few minutes to three hours after ingestion and initially present as violent gastrointestinal cramping with nausea, vomiting, and watery stools, followed by or associated with increased salivation, lacrimation, sweating, miosis, bronchoconstriction, an asthmatic type of dyspnea, a slow pulse, and at times shock. The pupillary response to light and accommodation may be decreased or absent, and there may be confusion, vertigo, convulsions, and coma. In some cases, psychic symptoms may be present and may even predominate. These are characterized by anxiety, hallucination, manic symptoms, dancing, singing, or a furious tremor. In general, these psychic symptoms pass in several hours and are followed by a period of somnolence. Although the majority of patients recover completely, a few may become comatose and die. The mortality rate in this general category of poisoning is extremely low, primarily because of the early onset of symptoms and hence the earlier treatment. Atropine is the treatment of choice and quickly abates the muscarinic symptoms, no matter if they are mild or severe. If death is to occur, it usually does so within the first hour.

Mycetismus Choleriformis (Delayed Type)

The deadly *A. phalloides* and *A. verna* are the responsible agents in this type of poisoning. In contrast to the rapid type of mycetismus nervosus mycetismus choleriformis involves symptoms of delayed onset, six to 15 hours after ingestion. The clinical picture presents in three phases. Initially, there is the explosive onset of severe abdominal pain, nausea, vomiting, watery diarrhea, melena, and severe dehydration with extreme thirst. This is believed to represent a direct irritative effect of the toxin on the gastrointestinal mucosa, although a muscarinic component may be present. Death may occasion-

ally occur during this initial stage, although usually the patient is seen soon enough and supportive therapy begun so as to prevent this. There may then occur a period of "false remission" wherein the patient's symptoms partially clear for a variable length of time, characteristically followed by worsening of the abdominal pains and then varying degrees of deterioration in hepatic, renal, and neurologic functions. The liver enlarges and becomes tender, and jaundice is noted along with abnormal findings on liver-function studies. Often there is a period of hyperglycemia followed by a more persistent hypoglycemia. This alteration in glucose metabolism is believed to be of hepatic origin. Pathologically the liver shows a generalized loss of architecture and massive areas of hemorrhagic necrosis. Renal involvement is clinically manifest as acute renal failure and, as with most similar cases, oliguria occurs and is followed in three to 17 days by diuresis. Deteriorating renal function is manifest by uremia, electrolyte and pH abnormalities, hematuria, and proteinuria. Pathologically, there is necrosis of both distal and proximal convoluted tubules but little involvement of the glomeruli. Electron microscopic studies have revealed enlargement of the mitochondria in the tubular cells and disruption of their membranes and cristae.¹⁵ Central nervous symptoms are varied, usually appear terminally, and are indicative of diffuse cerebral involvement. There may be somnolence, confusion, coma, convulsions, increased intracranial pressure, involuntary movements, and vasomotor collapse. Examination may reveal rigidity, tremor, hyperactive reflexes, bilateral Babinski's sign, ocular palsies, and on occasion meningeal signs. In addition, peripheral manifestations such as motor and sensory changes in the extremities are sometimes noted. Although a cursory pathologic study of the brain in *A. phalloides* poisoning was carried out in 1855 by Maschka, the first and most complete study was that of Marcovitz and Alpers in 1935.¹⁶ Prior to this time the manifestations of the central nervous system were attributed solely to hepatorenal failure, which was invariably present. These authors,¹⁶ however, demonstrated def-

MUSHROOM POISONING

inite pathologic alterations in the brain, consisting of marked cerebral and meningeal edema, degeneration and loss of pyramidal cells, areas of necrosis of white and gray matter, punctate cortical and brain stem hemorrhages, and toxic changes in the glial elements. Numerous investigators have since substantiated these findings. In addition to these pathologic changes, toxicity from *A. phalloides* is often associated with increased capillary fragility that leads to petechiae, retinal hemorrhages, and serosanguineous pleuritis, as manifested by a positive Rumpel-Leede test.* There may also be hemorrhagic necrosis of the myocardium.

The usual course of this disease is six to eight days in adults and three to four days in children. The mortality rate is high, estimated to be 50 to 90%. At times, 100% of those afflicted die, despite good supportive care.

Mycetismus Cerebralis (Psychotropic Mushrooms)

This classification was initially utilized by Ford¹⁴ to include symptoms produced by mushrooms of the genus *Panaeolus*. Symptoms consisted of transient exhilaration, immoderate laughter, peculiar visual disturbances, and staggering. These symptoms started four to five hours after the fungi were eaten and persisted for 24 to 48 hours. Other psychotropic mushrooms may be placed in this category because they produce symptoms similar to those just described.

A psychotropic agent is by definition any compound that produces psychotic phenomena in the presence of a clear sensorium. Psilocybin is one such drug and was isolated by Hofmann from the hallucinogenic mushrooms.^{17,18} It is a phosphorylated indole that is structurally related to serotonin and reserpine.

In three regions of the world men continue to eat mushrooms for their psychic effects. The *A. muscaria* is eaten in Siberia; in New Guinea certain tribes eat a mushroom called Nodda in preparation for battle or in times of sorrow or excitement; and in Mexico certain cults eat and worship

the *Psilocybe mexicana* and have done so since the time of Montezuma in 1502.

In a study of 22 volunteers at the Mayo Clinic¹⁹ psilocybin was noted to produce the following symptoms: initially, light-headedness, euphoria, anxiety, perioral paresthesia, blurred vision, increased vividness of visual images and colors, and increased auditory perception; first hour, dreamy state, euphoria, uncontrollable laughter, hallucinations of colored pattern with eyes closed; second hour, slowed passage of time, feelings of unreality and depersonalization, flashes of introspection, increased somatic perceptions; fourth hour, gradual waning of symptoms; and fifth hour, total resolution.

After total resolution there were no general side effects, although some reported an overwhelming fatigue and depression that persisted for 24 hours.

Disulfiram-Containing Mushrooms

Reports of toxicity due to the "inky caps" have appeared in the files of the State of Minnesota Health Department.⁶ Inky-cap mushrooms belong to the genus *Coprinus* and are given their name because of their black spores. In general, these are edible mushrooms. However, if alcohol is drunk within 24 hours after the mushroom has been eaten, toxic symptoms occur, which come on within minutes to two hours after the alcohol has been consumed and are identical with those produced by disulfiram (Antabuse). There may be flushing of the face, a feeling of warmth, a metallic taste in the mouth, hyperventilation, nausea, vomiting, sweating and tachycardia, and paresthesia. These symptoms are transient, usually clearing spontaneously. At times a severe reaction to disulfiram or acetaldehyde may occur, characterized by congestive heart failure, myocardial infarction, cardiac arrhythmias, respiratory distress, and convulsions. In 1956 disulfiram was isolated from these mushrooms by Simandl and Franc.²⁰

Treatment

In the majority of cases other than those due to *A. muscaria* and *A. phalloides* symp-

Continued

*See Test Your Word Score Page 521.

toms subside spontaneously without treatment. It is ideal for the attending physician to obtain parts of the offending mushroom for identification. However, this is not always possible as the mushrooms have usually been completely eaten, and even if recoverable their accurate identification is difficult. Pieces or spores may be recovered from the gastric aspirate, and at times these may serve as a source of identification. However, the physician's decision for treatment depends entirely upon the patient's history and symptoms. The most important consideration in the differential diagnosis is that between poisoning from *A. phalloides* or *A. muscaria*. In this regard, the time of onset is of great value. Poisoning with both types begins with explosive gastrointestinal symptoms; but in *A. muscaria* poisoning these occur within minutes to three hours after ingestion, whereas in *A. phalloides* poisoning their onset is delayed from six to 15 hours after ingestion. There is a suggested treatment for specific types of mushroom poisoning.

Atropine

A. muscaria or *A. pantherina*: Atropine is the treatment of choice and gives excellent results when both mild and severe symptoms are present. The dose is 0.6 mg. and may be repeated in one hour. Gastric lavage should be attempted, as this removes undigested mushrooms, and sedation with phenothiazines or barbiturates is useful when states of excitement or psychic symptoms are present.

Gastric Lavage

A. phalloides or *A. verna*: No specific antidote is available for this type of poisoning. Gastric lavage may be useful as late as 48 hours after ingestion; however, its value is questioned by some because the late onset of symptoms permits the fungi to pass well beyond the stomach. Instead, a vigorous catharsis seems more realistic and at times has been lifesaving. Atropine is of value, as the initial, explosive gastrointestinal symptoms may have a muscarinic character. Opiates can be given to relieve pain.

Intravenous Fluid

Intravenous feedings with glucose and electrolyte replacement should be initiated early because many of these patients are badly dehydrated and have lost electrolytes by vomiting and diarrhea. In addition, the alteration in glucose metabolism with initial hyperglycemia and the subsequent, more persistent hypoglycemia must be corrected, because the seizures that occur probably have a hypoglycemic basis.

Diet should be restricted to fruit juices, soups, tea, and sugar for at least 24 hours. The relatively high carbohydrate content of this diet is beneficial in the presence of hepatic involvement and is less irritating to an already irritated gastric mucosa.

Treatment of renal failure must include adequate hydration initially to distinguish between oliguria that is secondary to dehydration alone and that due to renal failure. If no response in urine volume occurs with hydration, there is probably renal tubular necrosis. If this is true, care must be taken not to overhydrate the patient. A daily intake of 400 ml. plus losses is recommended. Electrolyte imbalance, particularly hyperkalemia, should be noted and accurately corrected. Adequate amounts of glucose (150 to 200 gm./day) should be administered to minimize protein breakdown and hence potassium elevation.

Renal Dialysis

The value of renal dialysis has recently been discussed^{15,21} and seems to be of value in some cases. Elliott and associates²¹ described a case of mushroom poisoning in which successful treatment with hemodialysis was carried out. Myler and co-workers¹⁵ described two patients with *A. phalloides* toxicity who were treated with intermittent peritoneal dialysis; one patient survived, but the other died. The surviving patient was oliguric for 30 days and was treated with two 4-day courses of peritoneal dialysis. *Amanita* toxins are quickly bound to susceptible parenchymal cells. This fact plus the large size of the phalloidin or phalloin molecule makes the toxins poorly dialyzable. Therefore, successful use of dialysis has not

MUSHROOM POISONING

been attributable to removal of the toxin per se but instead to a supportive role during temporary periods of renal failure. Myler and associates¹⁵ considered intermittent peritoneal dialysis to be more desirable than hemodialysis, although it is a much slower process. Peritoneal dialysis allows for a simultaneous adjustment of electrolytes and glucose, whereas hemodialysis does not. Also, the large molecule of the toxin passes more easily through the peritoneal membrane than through the cellophane membrane of the hemodialysis apparatus.

Other Treatments

In the treatment of poisoning associated with myocardial involvement, digitalis is used.

Another technique includes the use of sensitized rabbit stomach and brain. In 1932 Limousin and Petit¹ noted that rabbits died of phalloidin toxin when the agent was given parenterally but not when it was given orally. Rabbits then were "sensitized" with orally administered phalloidin. Minced

rabbit stomach plus raw rabbit brain was then given to cats. This mixture seemed to protect the cats against poisoning. Similar attempts were carried out with humans who received various proportions of sensitized rabbit stomach and rabbit brain. To date this has been ineffective and not used in this country.

Antiserum has been used by some. Rabbits and horses were sensitized with progressively increasing doses of toxin, and their serums were found to have antitoxic qualities. This antiserum has been highly acclaimed in the French literature although it is believed by most in this country to be of limited value. Antibodies to *A. phalloides* have never been demonstrated.

To relieve the symptoms incurred from psychotropic mushroom poisoning, chlorpromazine hydrochloride is effective.

Transfusion helps hemolytic mushroom poisoning. In poisoning from disulfiram-containing mushrooms, treatment is necessary only for the severe reactions, in which cases oxygen inhalation and orally administered ephedrine are of value.

**How long will
it take her
to recover from
her hip fracture
if she just
doesn't care?**

**Does she really care?
Is she alert, encouraged,
positive and optimistic
about getting completely
well soon?**

**Or has she given in to
the demoralizing impact
of confinement, disability
and dependency?**

**When functional fatigue
complicates convalescence,
Alertonic can help...**

Pleasant-tasting Alertonic is pipradrol hydrochloride—an effective cerebral stimulant whose gentle analeptic action helps counteract the apathy and inertia that can often delay convalescence—together with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding and encouragement together with Alertonic to help insure prompt response.

*Adequate dosage is important: Prescribe Alertonic—
one tablespoonful t.i.d., 30 minutes before
meals...tastes best chilled.*

*And for your patient's sake, prescribe Alertonic
in the convenient, economical one-pint bottle.*

Alertonic[®]

Available Only On Prescription

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B₁) (10 MDR*), 10 mg.; riboflavin (vitamin B₂) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B₆), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.

†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Treating the Patient Who Has Convulsions*

PATIENTS WHO suffer from convulsive disorders far outnumber other types of neurological patients. The estimate that one out of every fifty humans will have some form of seizure disorder during his lifetime is probably conservative. Convulsive disorder patients come to medical practitioners in numbers which exceed the much more publicized "stroke" patients. It is also true that for each one who comes under medical care for this disorder there are others who go undiagnosed and still others who go to great lengths to hide the fact that they have the disorder even from their physicians. It is definitely the most common disorder of the central nervous system of man.

For several decades now the medical practitioner has had innumerable books and articles available to him on the subject of convulsive disorders. The more subtle forms of focal motor, sensory and visual seizures have been described, classified and then described further. Psychomotor or limbic lobe seizures have been widely publicized for the past fifteen years. There remain few if any doctors who are unaware of the etiological possibilities for this malady; certainly all are aware of the role of brain tumors. The anticonvulsants have not been neglected; literature has fought to describe the newer ones sometimes even before the pills "have dried." Full-page advertisements and "detail" men have publicized the merits of products with most convincing scientific proof, usually in chart form. The diagnosis and treatment of the convulsive disorder has probably been covered "too well" in recent times and the "treatment of the *patient* with a convulsive disorder" discussed not at all.

The usual patients with seizures are those who do not have brain tumors or a "long-named" central nervous system degeneration. Most frequently they have had their peculiar paroxysms recurrently from early life due to a "scar" on their brain from an infection or trauma. Many have gone weeks to years between seizures, only to have them recur. The treatment of this group is not always easy and those who endeavor to do a good job of it find no help in the literature on the common problem of recurrent seizure activity.

The difficulty arises in most seizure patients shortly after they have been diagnosed and placed on anticonvulsants. They then proceed to have another convulsion. At first the physician confidently increases the dosage of the anticonvulsant or changes to another agent. After a variable period of time the patient again has another convulsion. This pattern often continues until toxic doses of anticonvulsants are being used. Both the physician and the patient are discouraged by the result. Consequently many physicians "give up" trying to treat these patients, and many a patient discontinues treatment because its effects are worse than the disease.

*Presented at the Black Hills Medical Seminar, August 5, 1966.

Continued

The basic fact that anticonvulsants are effective and remain so even when a seizure breaks through must be remembered; no tolerance or loss of potency of their medicine occurs in the seizure patient. A "therapeutic regime" is the amount of medication that a patient may take with benefit but which does not interfere with his usual activity. "Therapeutic regime" does not mean an amount of medication that causes over-sedation, diplopia, ataxia or inebriation. Maximum anticonvulsant benefit in the treatment of major seizures can usually be achieved by the administration of diphenylhydantoin (Dilantin) 300 mg. per day, mephobarbital (Mebaral) 300 mg. per day, and primidone (Mysoline) 750 mg. per day in total dosage or in varied and lesser amounts. Once this level is achieved and the patient returns, after having had another seizure, what can the physician do?

When this patient reports another seizure do not reach for the prescription pad; instead, inquire about a few general factors that often influence seizure activity. These are fatigue, infection, changes in medication, toxins and hydration.

Very often a patient who has been well controlled for weeks or months and then has a seizure does so because of an infection. The common cold, an otitis, a pharyngitis, a bout of "flu" or any other infection may be the cause of the difficulty, and a history regarding infections must be taken in this type of patient. Frequently the patient has continued his usual activity, admitting only to "feeling miserable" and to having "kept working", but with an obvious infectious process. The lowering of the seizure threshold by an infectious process is to be expected, and when the infection is cured there is no need to increase the anticonvulsants. It is far wiser to treat the next minor infection vigorously with bed rest and appropriate agents so that the convulsive disorder does not "break through" a second time.

Equally as often, when a patient develops recurrent seizures for no apparent reason, the cause will be fatigue. The socioeconomic stresses and the difficulty of getting and holding a good job frequently force these patients to work long hours or at two jobs in order to support themselves and their families. This results in less than adequate sleep, and chronic fatigue results, producing many "supposed" treatment failures. Fatigue occurs on another basis as well. Socioeconomic stress frequently results in considerable marital discord and anxiety in seizure patients and many suffer from insomnia, resulting in poor seizure control due to chronic fatigue. In none of these patients will increasing the anticonvulsants counteract the fatigue and be of benefit. The only way to reduce fatigue is to rest. Rest does more to fortify the brain's own physiological deterrents to seizure activity than even anticonvulsants, and to achieve optimum seizure control every patient must have eight hours of sleep every night!! If sleep is lost for one night due to an emergency it must be "made up" at the earliest possible moment. During a state of fatigue seizure control is precarious.

A surprising number of patients who return to the physician with complaints of seizures do so because they have failed to take the medications or have reduced or discontinued them. They usually fail also to volunteer this information for obvious reasons: a point that must not be forgotten. These seizure patients often have a poor understanding of

the convulsive state; many feel they have the evil "biblical epilepsy" and society still treats them this way. They frequently try to deny their malady by decreasing or discontinuing their medications: the most concrete method of denial. A discussion of a "scar on their brain" and its need for continued medication is most necessary.

Another group of patients who return with recurring seizures while taking adequate medication is not quite so clear-cut. This includes a number of female patients who tend to have an aggravation of their seizures prior to or during the menses and who do not benefit from increased amounts of anticonvulsants. The value of diuretics in this group suggests that their fluid balance may in some way be involved and indicates a good method of treatment. The condition is never severe enough to necessitate oophorectomy. Others in this group develop recurrent seizures only after bouts of excessive drinking, usually alcoholic. The period of the "hang-over" and of excessive thirst is a period of seizure aggravation. Optimal seizure control is not possible in patients who persist in bouts of very heavy drinking. The socioeconomic stresses of the seizure patient are often so great that they foster alcoholism, which only compounds the problem; therefore it is wise to strongly discourage alcoholic consumption in seizure patients.

Emotional stress, anger, fear, sorrow or shock do not account for seizure aggravation, except when they result in chronic fatigue of the patient. The physiologic need of the brain for adequate rest plays an important role in convulsive activity, and stress frequently interferes with adequate rest.

To successfully treat the patient with a convulsive disorder requires the judicious use of drugs below sedating levels and close attention to general factors that play an important role in clinical aggravation: namely, fatigue, infection, and auto-regulation of medicine and alcohol.

Many overweight patients can benefit from the appetite control provided by the sustained anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action of amphetamine; tranquilizing action of meprobamate; prolonged action through sustained release of active ingredients.

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.) SUSTAINED RELEASE CAPSULES
WITH MEPROBAMATE (300 mg.)

**to help establish
a new dietary pattern**

Contraindications: Dextro-amphetomine sulfote: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetomine sulfote: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetomine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), onophyloxia, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

LEDERLE LABORATORIES

AMA • 116th Annual Convention • Atlantic City, New Jersey • June 18-22, 1967

Come to Atlantic City—one of America's favorite by-the-sea playgrounds—and join your colleagues at the AMA's 116th ANNUAL CONVENTION!

Fine hotels and motels, excellent restaurants, plus all the advantages of a lively resort make this year's Convention a must for you and your family. Atlantic City provides a superb setting for a summer classroom and all the latest techniques of modern medicine. Plan to be one of the participants in this rewarding four day postgraduate education program.

• Four general scientific sessions • 23 section programs • 575 scientific and industrial exhibits. Lectures, panel discussions, motion pictures, and color television. Plan to attend—continue your postgraduate education.

RESERVE NOW for the SCIENTIFIC AWARDS DINNER in honor of the Scientific Award Winners—Wednesday, June 21, 1967. Since space is limited, we suggest you make your reservations before June 1, 1967. Tickets are \$10.00 each, payable in advance.

See JAMA May 8, 1967 for complete scientific program—forms for advance registration and hotel accommodations.

Bacteremia Due to Gram-Negative Bacilli

Some Current Concepts. Part II*

Supportive Therapy

CONSIDERABLE CONTROVERSY exists regarding ancillary management of these infections, especially in regard to antishock regimens, but the measures that are frequently employed are mentioned at least for the sake of completeness. Although any outline of therapy is controversial, different regimens are being employed in several medical centers and comparative data will become available. At the outset, it should be recalled that differences in animal species, especially those between the canine and human, in their reactions to endotoxin, make it extremely difficult to relate experimental data to clinical phenomena in a precise manner. Use of various agents to improve blood flow and tissue perfusion in bacteremic shock cannot be directed by generalization but depends upon precise identification of hemodynamic derangements present in the individual patient.

Important among supportive measures is the management of fluid and electrolyte deficits. Although parenteral glucose appears to prolong life in experimental animals, overadministration of fluids, especially of saline, during oliguria can embarrass cardiac function and induce pulmonary edema. Of course, if hypovolemia is present in the case at hand, it should be corrected. Measurement of central venous pressure indicates the competence of the heart to accept and expel a given blood volume and may serve as a guide to volume repletion. Fluid can be cautiously given as long as the central venous pressure is low or normal, that is, 5 to 15 cm. of water.

Replacement of blood may be required in

such patients as those having bleeding lesions of the gastrointestinal tract or underlying hematologic disease. In these patients it is conceivable that reduced blood volume predisposes them to the development of shock from bacteremia due to endotoxin-producing gram-negative bacilli as is suggested in certain animal experiments.

Antiacidotic measures are being investigated, and while acidosis can be corrected by infusion of sodium bicarbonate, levels of blood lactate appear to be uninfluenced unless peripheral circulation is improved concurrently. Use of other buffering agents in patients having lacticacidosis, such as tris (hydroxymethyl) aminomethane or THAM, may have application in the future. An isotonic solution of THAM (36 Gm. in 1,000 ml.) may be given intravenously during one- to two-hour periods. A possible means of lowering blood levels of lactic acid may be the administration of 5% carbon dioxide in oxygen. Also there are experimental data that one may reduce lacticacidemia by administration of dihydroxyacetone, a product of glucose metabolism which transforms lactic acid into pyruvic acid.

The gallbladder, postoperative wounds, obstructive uropathy, and so forth may constitute nidi of infection from which the blood is reseeded with organisms, and surgery may be required. One attempts to control the bacteremia before subjecting the patient to added stress, but sometimes bacteremia persists until such a nidus is attacked surgically. Metastatic suppuration requiring surgical attention most often complicates *Bacteroides* bacteremia.

Vasopressors have been used in an attempt to restore circulating homeostasis by rein-

Continued

*Read at the meeting of the American Academy of General Practice, Lake Okoboji, Iowa, June 18, 1966.
See Part I, Minnesota Med 50:397, 1967.

forcing the natural bodily reaction to prevent so-called irreversible shock, and also to forestall renal ischemia and renal shutdown. Use of a vasopressor is a temporary supportive measure until other therapeutic procedures and the patient's own compensatory mechanisms are able to maintain adequate blood pressure and tissue perfusion. Of the numerous vasopressor agents available, those which have been used most commonly in the recent past are metaraminol, levarterenol, and angiotensin. Of course, a current question is whether vasodilators should be used rather than vasopressors.

Prior to the discussion of vasoactive drugs, it may be well to review some of the terminology currently employed in describing these agents and their actions. There are two types of adrenergic receptors situated in the vascular system: alpha and beta. Alpha-adrenergic receptors mediate vasoconstrictor responses while beta receptors mediate vasodilatation. Thus, levarterenol may cause vasoconstriction by stimulating alpha receptors in blood vessels, while isoproterenol may cause vasodilatation by stimulating beta receptors. In addition, both levarterenol and isoproterenol may cause positive chronotropic effects (increased cardiac rate) and positive inotropic effects (increased myocardial contractility) via their action on the heart. Alpha-adrenergic blockers (alpha-receptor blockers), which may antagonize vasoconstrictor effects, are exemplified by phenoxybenzamine and phentolamine.

Metaraminol (Aramine) can be given intramuscularly, but preferably is given intravenously, in amounts of 100 to 250 mg. in 500 to 1,000 ml. of fluid. Experimental data suggest that the release of levarterenol from sympathetic nerves has a major part in the action of metaraminol. Therefore, when refractoriness to metaraminol is suspected, one substitutes levarterenol. Reserpine may deplete bodily stores of levarterenol, with consequent reduced response to metaraminol.

Levarterenol or norepinephrine (Levophed) is given intravenously in increments of 4 ml. of a 0.2% solution in 1,000 ml. of 5% dextrose in distilled water at a rate sufficient to maintain the desired blood pressure.

Fluids containing dextrose protect against loss of levarterenol's potency due to oxidation; levarterenol should not be given in saline solution alone. More than a dozen ampules have been given in one day to patients who remain hypotensive. Use of leg veins in patients with arterial disease and use of hand veins are avoided, and the site of infusion and the course of the vein infused are observed for local ischemia. If blanching occurs, necrosis is minimized on stopping the infusion and infiltrating the area with adrenergic blocking agents such as phentolamine or piperoxan. Protection against local necrosis may follow addition of 5 to 10 mg. of phentolamine or of 10 to 20 mg. of heparin to each liter of solution containing the agent. Levarterenol and metaraminol increase peripheral resistance and stimulate the myocardium. In contradistinction to the reaction in normal subjects, in patients who are in shock administration of these drugs tends to increase cardiac output.

Angiotensin (Hypertensin) has maintained the blood pressure satisfactorily during bacteremic shock. Although angiotensin has been given intramuscularly, usually it is given intravenously. A vial of angiotensin contains 2.5 mg. of the drug, and one to four vials are added to 500 to 1,000 ml. of fluid; as many as 10 vials have been given in a 24-hour period. Angiotensin directly increases peripheral resistance without affecting the heart; the action of angiotensin appears to be independent of adrenergic receptors. Patients not responding to levarterenol have responded to angiotensin, but since the converse also occurs, in some patients a trial of both drugs is required.

A Y-tube apparatus used to give a vasopressor intravenously allows its periodic discontinuation so that only the minimum is consumed, and yet it is immediately available if hypotension occurs. Similar titration is not possible with vasopressors given intramuscularly. When vasopressors are given, it is unnecessary to raise the systolic blood pressure above 100 mm. of mercury in a previously normotensive patient.

As aforementioned, vasodilators, including alpha-adrenergic blocking agents,¹³ are being

investigated in place of vasopressors in patients having bacteremic shock. Proponents of their use point out that pallor, sweating, and tachycardia reflect vasoconstriction, and these workers discourage administration of vasopressor drugs because of concern that a further reduction in systemic blood flow might result. They postulate that dilatation of blood vessels rather than their further constriction by vasopressors is required to relieve visceral pooling. These workers have concluded that the body's attempt to preserve blood supply to vital centers such as the heart and brain at the expense of other areas is undesirable; they consequently give a vasodilator to undo the reaction. Some of these workers emphasize that this intensified vasoconstriction may be responsible for decreasing renal blood flow and urinary output; but if over-all measures do not correct the underlying cause of the shock, increased urinary output, as an isolated achievement, is less than a therapeutic triumph. Phenoxybenzamine (Dibenzylamine) administered intravenously in amounts of 1 mg. per kg. of body weight is commonly recommended by these investigators; but this form of the drug is not commercially available. Although use of phenoxybenzamine may increase the urinary output, it may also further reduce the blood pressure and require administration of blood or its products or a plasma expander to combat the increased hypotension. For this reason, it is recommended that vasodilators be used only when effective circulating blood volume is known to be normal or is being replaced.¹⁴ Some workers recommend administration of a vasodilator when there is increased central venous pressure, decreased cardiac output, and pulmonary congestion; but these findings also might be interpreted as indications for digitalization. Despite considerable discussion based on animal experimentation, there are little data on the efficacy of alpha-adrenergic blocking agents in the management of human victims of bacteremic shock. Eckenhoof and Cooperman¹⁵ gave phenoxybenzamine to 24 patients, six of whom died; excessive vasodilatation was considered a contributory factor in the deaths of five of these six patients. Phentol-

amine (Regitine) is also an alpha-adrenergic blocking agent which has been employed for its vasodilating effect.

Isoproterenol (Isuprel) is chemically related to epinephrine and levarterenol and, as aforementioned, is a so-called beta-receptor stimulator. The drug is used in cardiogenic shock and is currently being reevaluated in bacteremic shock.¹⁶ Unlike its chemical relatives, isoproterenol may induce peripheral vasodilatation. Monitoring of cardiac rhythm is advised during administration of the drug since arrhythmias may result from its inotropic effect. Isoproterenol is given intravenously in an initial dose of 2.5 mg. in 500 ml. of 5% dextrose in water at a rate of 0.5 to 1 ml. per minute. If no reaction occurs within 15 minutes, the rate of infusion is doubled.

Other vasodilators that have been recommended include trimethaphan (Arfonad) and hydralazine (Apresoline).¹⁴

There is some reticence to abandon the use of vasopressors because evidence exists that the mortality rate is less for patients having bacteremic shock who receive vasoconstrictor drugs. Hall and Gold¹⁷ reported a mortality rate of 57% for 21 patients who received no vasopressor drugs and 36% for 14 patients who were given these agents. Hodgkin and Sanford¹⁸ in their more recent study also concluded that use of vasopressor agents was of value in bacteremic shock. A possible basis for the discrepancy in opinions regarding the use of vasopressors is that less than desirable results have been noted in patients who have reached stage II of shock. In an attempt to reconcile the data at hand and to provide a temporary scheme, enabling one to make a clinical decision regarding the use of vasoactive drugs in a given instance, the following generalizations may be helpful until more concrete data are available. Vasopressor drugs may be employable in patients with bacteremic shock when blood volume deficit is safely excluded as the cause of shock. If the patient does not respond to such management after a reasonable interval, use of a drug such as isoproterenol may be considered. However, it

Continued

should be emphasized that one must guard against losing valuable therapeutic time while procuring multiple electrocardiograms, awaiting the results of elaborate laboratory procedures, and belatedly diagnosing bacteremic shock when the patient has not responded to regimens more pertinent to noninfectious shock. If bacteremic shock is not diagnosed early and if adequate antibiotic therapy is not quickly initiated, no supportive treatment, including use of vasopressors or vasodilators, will have optimal effect.

Oxygen therapy tries to counteract tissue anoxia due to reduced arterial blood flow, and although it is helpful in experimental animals, the logic of its clinical use is disputed. Hyperbaric oxygenation also has prolonged life in experimental animals. High-pressure oxygen therapy may increase oxygen transport to the tissues and also have a bacteriostatic effect on the infecting bacilli. A major objection to the clinical use of hyperbaric oxygenation is the possibility of fatal oxygen toxicity involving the pulmonary and central nervous systems.

An airway is provided if necessary.

Digitalization of the hypotensive patient is carried out only if the central venous pressure remains above 15 cm. of water and particularly if other evidences of heart failure, such as pulmonary edema, are detected. Digitalization can be carried out by giving 0.5 to 1 mg. (2 to 4 ml.) of digoxin intravenously and then 0.25 mg. every two to four hours; full digitalization may be achieved after a total of 1 to 1.5 mg. is given. It is to be recalled that in human bacteremic shock many of the affected patients are elderly and their cardiac function may be compromised by coronary atherosclerosis and other types of heart disease.

Such mechanical measures as elevating the foot of the patient's bed and applying an abdominal binder and leg bandages may increase venous return and cardiac output. However, there are no exact data indicating that these measures are of substantial benefit.

The exact application of hypothermia¹⁹ in bacteremic shock remains unclear although

it has been helpful in experimental animals. The rationale for hypothermia is based on reduction of the need for cellular oxygenation, thereby favorably influencing the metabolic environment. If hypothermia is not used, the patient is kept comfortably warm; but overheating, which may dilate superficial vessels and further increase the capacity of the vascular bed, is avoided.

In cases wherein hypotension is prolonged, renal shutdown may occur. Usually recovery from renal shutdown is heralded by reappearance of excretory function within 10 to 12 days. However, excretory function reappears before regulatory function, and death with progressive azotemia and acidosis remains possible. Hemodialysis has contributed to maintaining life and reducing morbidity during the oliguric phase of renal shutdown. It should not be reserved as a last desperate measure, since its failure to prevent death may reflect belated use. In this same regard, there are data indicating that renal failure which is partial or incipient may be reversed by the use of mannitol intravenously. Significant diuresis is an average increment in urine flow of more than 0.2 ml. per minute in three hours after 25 gm. of mannitol is given intravenously. If less than 50 ml. of urine is produced in the next two hours, no more mannitol should be given. The mechanism of mannitol diuresis appears to be acute expansion of blood volume with subsequent increase in glomerular filtration rate. Lack of significant diuresis after administration of mannitol usually indicates fully developed renal shutdown. Mannitol may produce transient vacuolization of the proximal tubules, but this does not appear to be associated with changes in renal function and therefore is not considered significant. It is advised that concentrates of mannitol not be given in the presence of hyponatremia or hypochloremia; their use also is inadvisable in the presence of congestive heart failure.

Use of morphine, meperidine (demerol), barbiturates, and other depressants is best avoided.

Use of adrenal glucocorticoids has been advocated despite the fact that these pa-

tients, even when moribund, show no abnormality of the secretory function of the adrenal gland.^{20,21} Some investigators oppose administration of vasopressors on the basis that the adrenal glands are capable of providing these in sufficient quantity; but contrariwise, some of these workers give massive doses of adrenal glucocorticoids despite no evidence of adrenal insufficiency. On reviewing mortality rates in reported series wherein steroids were used, one might conclude that patients receiving them have a higher mortality rate. McCabe and Jackson² concluded that the effects of adrenal glucocorticoids in their patients were adverse. Known complications of steroid therapy include impairment of the immune response and an increased susceptibility to upper gastrointestinal bleeding; the latter complication can lead to considerable diagnostic and therapeutic confusion. Such bleeding occurs spontaneously in victims of bacteremic shock and may be potentiated by steroids. An additional objection to the use of such therapy is that, on analysis of the causes of death in patients having bacteremic shock due to gram-negative bacilli and given adrenal glucocorticoids, a complicating staphylococcal superinfection is not uncommon. My colleagues and I have limited administration of adrenal glucocorticoids in nonpharmacologic dosage to those patients who were receiving them prior to the onset of bacteremia.

Also, we have not used blood or its products in the definitive management of this complication because in the usual case of bacteremic shock there appears to be no decrease in blood volume but rather stagnation and faulty redistribution of it. It is recognized, of course, that replacement of blood may be required in such patients as those having bleeding lesions of the gastrointestinal tract or underlying hematologic diseases. On the other hand, a rapid intravenous infusion of 500 ml. of low molecular weight dextran,²² in patients with a normal central venous pressure but low cardiac output and hypotension, appears to be relatively safe and may normalize the circulatory dynamics without resorting to a vasopressor or a vasodilator. Depending on individual circum-

stances, the dextran has been given over periods ranging from 30 to 120 minutes; 500 ml. can be administered slowly over subsequent 12-hour periods. Low molecular weight dextran (40,000) is available only for investigation in the United States; the molecular weight of dextran usually employed in this country is 75,000. Higher molecular weight dextrans (110,000 and up) are also being employed by some investigators. Normally, dextran 40 is excreted in one to two hours, but in shock its excretion may be prolonged to four hours or longer. Administration of the agent may increase cardiac output, decrease peripheral resistance, and restore urinary output.

Heparinization to counteract intravascular coagulation during experimental bacterial shock has been advocated, but its benefit also lacks clinical confirmation. Numerous other regimens, including testosterone, aldosterone, serotonin antagonists, chlorpromazine, and even antihistaminics, have been described as being helpful in experimental animals, but this does not automatically assure their efficacy in the human subject.

Overemphasis of a unitarian concept of shock with insufficient attention to etiologic differences may lead to regimens largely based on wishful thinking. At this time, there is no one regimen equally applicable to such diverse etiologic entities as cardiogenic, hemorrhagic, and bacteremic shock. Cardiac support and replacement of blood do not influence the basic defect in the usual case of bacteremic shock, and these and other symptomatic procedures are designed only to maintain the patient's life until antibiotic therapy can control the overwhelming infection which is the essential cause of his vascular collapse. It is appreciated, of course, that patients with such underlying conditions as coronary artery disease and bleeding lesions of the gastrointestinal tract may require special attention in this regard, but these isolated requirements hardly justify universal administration of digitalis and blood. When there is a diagnostic and therapeutic difficulty, as exemplified by the patient with underlying hematologic disease in

Continued

whom shock suddenly develops, monitoring of the central venous pressure and determination of the hematocrit value may aid one in deciding about the advisability of blood replacement. If in such a patient, on administration of blood, the central venous pressure rises abruptly, the transfusion can be stopped and phlebotomy carried out by the same route, that is, the central venous catheter. Consequently, it is possible to act in an empiric manner and yet undo potential harm before it has become catastrophic. When an investigator states that he employed antibiotics in the management of bacteremic shock, it would be helpful for comparative analysis if he were to make clear the dosage and duration of such therapy, as well as the specific drugs employed, and perhaps most importantly the time consumed between the onset of infection and the initiation of antibiotic therapy. If antibiotic therapy is inadequate, the essential cause of bacteremic shock is not being combated, and consequently therapeutic success is unlikely.

Prognosis

The prognosis is considerably determined by the nature and severity of the initial lesion, the presence of underlying disease, prior therapy, the duration of the infection before institution of appropriate management, and complications such as bacteremic shock, metastatic infection, and superinfection.

Patients who recover usually have had the benefit of early diagnosis and treatment. Since the commonest precipitant of bacteremia is urethral manipulation, including catheterization, such "potential candidates" must be recognized and managed accordingly to assure the best prognosis. Along with monitoring of the candidate's temperature and pulse rate, hourly determinations of the blood pressure and recording of the urinary output appear to be the best routine objective indices of his current status.

In our experience, the majority of deaths have occurred in cases of serious associated conditions, and in at least 50% of fatalities the associated condition was responsible. In this regard, one should be prepared to encounter the potential paradox that as man's

ability to prolong life improves, his success in the management of bacteremia due to gram-negative bacilli may decrease. This is so because the underlying disease predisposing to infection may so diminish host resistance that recovery is virtually impossible, at least within the present limits of therapy.

Summary and Conclusions

Only about 10% of the cases of bacteremia due to gram-negative bacilli occur in the absence of underlying disease, therapy capable of altering host resistance to infection, or precipitating operation or instrumentation. In managing any patient with possible predisposing disease or treatment — especially a patient with disease of, or recent operation on, the urinary or gastrointestinal tract who has fever — one should be constantly aware of the possible presence or supervision of bacteremia and, consequently, bacteremic shock due to gram-negative bacilli.

Empiric antibiotic therapy is begun when report of cultures is received or, in seriously ill patients, after blood is drawn for cultures. If the patient's condition and microbiologic data later indicate such empiric therapy to be unsatisfactory, it is modified accordingly. Use of specific antibiotics in the initial management of gram-negative bacteremia is only theoretically possible because, practically, one is often thwarted by lack of cultural proof of the pathogen and, almost always, of its in-vitro susceptibilities. In little more than one third of our cases did the usual circumstances surrounding such infections, including the intrinsic delay in the reporting of in-vitro bacterial susceptibilities, allow use of a single drug. However, these difficulties are not of such magnitude that one cannot devise adequate antibiotic therapy on an empiric basis. If such a regimen is not employed, or not employed early in the infection, the essential problem is not being attacked and recovery is unlikely.

To the present, the majority of our patients having bacteremic shock have received a vasopressor, most commonly levarterenol, and antibiotic therapy; they have not received steroids as definitive therapy. Since the mortality rate in patients, managed in

this manner, is lower than has been reported in certain series in which other regimens were employed, members of our group plan to continue management of bacteremic shock in this manner, at least until sufficient data are available which would make a change in therapy reasonable. At the same time, we are continuing our evaluation of cephalothin-colistin (or cephalothin-poly-myxin B) as empiric antibiotic therapy, isoproterenol (Isuprel) as an antihypotensive agent, and the rapid infusion of dextran in place of a vasoactive drug in selected patients. Perhaps more important than the investigation of new regimens is the recognition of the potential candidate and the monitoring of his temperature, blood pressure, and urinary output, so that early diagnosis and treatment of the complication are possible. It is our experience, too, that when stage II of shock has been reached, optimal response to therapy, including vasopressor therapy, is less likely. Such factors as blood loss and impaired cardiac function undoubtedly play a part in individual cases of bacteremic shock, and in such cases, therapy

should encompass these considerations, but this does not appear to be a reasonable basis for recommending that these therapeutic facets be generally applied.

In conclusion, there appear to be several possible explanations for the rather marked differences in mortality rates of various series of patients having bacteremia and bacteremic shock due to gram-negative bacilli, and consequently for the controversies regarding management of these infections. These include (1) delayed diagnosis with consequent failure to initiate pertinent treatment early in the process, (2) inappropriate antibacterial therapy, (3) the type of patient concerned, since those with serious underlying diseases are less likely to recover, (4) reliance on experimental data which may not be applicable to the human subject, (5) overemphasis of a unitarian concept of shock with insufficient attention to the particular cause of infectious shock, and (6) attempts at supportive therapy which may be of questionable value or perhaps actually militate against host defenses.

They Say

Public opinion is a jurisdiction which the honest man must never fully recognize, and which he must never ignore. — Chamfort

Futility

Futile as is the search for perpetual motion, the search for perpetual rest is still more so. — Panin

"George wants to know if it's okay to take his cold medicine now, Doctor, instead of seven o'clock?"

The long-continued action of Novahistine LP should help you both get a good night's sleep. Two tablets in the morning and two in the evening will usually provide round-the-clock relief by helping clear congested air passages for freer breathing. Novahistine LP also helps restore normal mucus secretion and ciliary activity—normal physiologic defenses against infection of the respiratory tract. Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

NOVAHISTINE[®] LP

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis

You can't set her free. But you can help her feel less anxious.

You know this woman.

She's anxious, tense, irritable. She's felt this way for months.

Beset by the seemingly insurmountable problems of raising a young family, and confined to the home most of the time, her symptoms reflect a sense of inadequacy and isolation. Your reassurance and guidance may have helped some, but not enough.

SERAX (oxazepam) cannot change her environment, of course. But it can help relieve anxiety, tension, agitation and irritability, thus strengthening her ability to cope with day-to-day problems. Eventually—as she regains confidence and composure—your counsel may be all the support she needs.

Indicated in anxiety, tension, agitation, irritability, and anxiety associated with depression.

May be used in a broad range of patients, generally with considerable dosage flexibility.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. One patient exhibiting drug dependency by taking a chronic overdose developed upon cessation questionable withdrawal symptoms. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose; excessive prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Safety for use in pregnancy has not been established.

Not indicated in children under 6 years; absolute dosage for 6 to 12 year-olds not established.

Side Effects: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age.

These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever, euphoria and dysmetria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam.

To help you relieve anxiety and tension

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

In Memoriam

It is impossible that anything so natural, so necessary, and so universal as death, should ever have been designed by Providence as an evil to mankind. — Swift

ARNOLD LARSON, M.D.

Dr. Arnold Larson, 73, a resident of Detroit Lakes for thirty-eight years and a practicing physician and surgeon for thirty-six years, died January 25. Born in Fillmore County, Dr. Larson received degrees at both the University of Minnesota and the University of Pennsylvania.

He was a member of the Clay-Becker County Medical Society and the American Medical Association. He was a Life Member of the Minnesota State Medical Association and an active member of the Kiwanis Club and Masonic Lodge.

Dr. Larson is survived by his son and two daughters.

JOHN PETER FREEMAN, M.D.

Dr. John Freeman, 90, a lifetime resident of Glenville, died February 2. A practicing doctor since 1900, Dr. Freeman retired in 1960. He was a graduate of the University of Illinois Medical School.

Dr. Freeman was a member of the Freeborn County Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife, a son and a daughter.

JESSE P. NEHRING, M.D.

Dr. Jesse Nehring, 63, Preston physician, died January 25. A native of Belgrade, Dr. Nehring graduated from the University of Minnesota Medical School in 1929 and immediately went to Preston where he practiced medicine for thirty-eight years.

He was the Fillmore County coroner, county public health officer and medical examiner for the Selective Service. Dr. Nehring was a member of the National Academy of General Practitioners, the Zumbro Valley Medical Society, the American Medical Association, the Minnesota Academy of General Practitioners, the Southeastern Minnesota Medical Society, and the Minnesota State Medical Association.

He is survived by his wife, three daughters and a son, Dr. John D. Nehring of Wabasha.

RAYMOND T. HEALY, M.D.

Dr. Raymond T. Healy, 83, family physician in Pierz for fifty-five years, died February 14. Born in LeSueur, Dr. Healy received his medical degree from the University of Minnesota. He served for one year on the State Board of Health in Minneapolis and went to Pierz in 1912. Pierz honored him on his 50th year in that community, and Healy Junior High School was named in his honor.

He served on the medical staff of St. Gabriel's hospital, Little Falls, was a member of the Upper Mississippi Medical Society and the American Medical Association. He was a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

JOHN A. WINTER, M.D.

Dr. John A. Winter, 87, an eye, ear, nose and throat specialist in Duluth, died February 15. Born in Nagaunee, Michigan, Dr. Winter graduated from the University of Michigan in 1902. Four years later he entered Johns Hopkins Medical School where he studied under the famed Sir William Osler. Serving his internship in Chicago, Dr. Winter practiced for two years in Calumet, Michigan, before journeying to the University of Vienna in Austria to advance his education in his specialty.

A year later he returned to the Illinois Charitable Eye and Ear Infirmary in Chicago. In 1910 he went to Duluth and launched his practice. Dr. Winter and his seven colleagues established the Duluth Clinic in 1915.

He was a member of the St. Louis County Medical Society, American Medical Association, Minnesota Academy of Ophthalmology, American College of Surgeons and the American Academy of Ophthalmology and Otolaryngology. Dr. Winter was a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by two nieces and two nephews.

Regardless of Mother's Opposition

I had always wanted to be a doctor like my father before me. The story goes that I came into the house one day when I was about six and announced that when I grew up I was going to be a big fat doctor. Mother just shook her head. She knew only too well the wearisome toil, the long hours with broken sleep, the heavy responsibilities, and the sheafs of unpaid bills that play so large a part in a doctor's life. Father knew these things, too; he never encouraged me or discouraged me.

One day when I was thirteen and we were alone in the office, I told Father that I had fully made up my mind to be a doctor regardless of Mother's opposition. He listened to what I had to say in grave silence, eyeing me thoughtfully over his glasses.

"All right. I'll take you along with me to-morrow," he said.

So the next morning I drove him to the home of an old gentleman I knew well whom I had always seen wearing a long white beard. When I saw him with his beard shaved off and a big, repulsive looking epithelioma protruding from his lower lip, I admit I was shocked. While another doctor administered the anaesthetic my father removed the cancer and the entire lower lip with it. The sight of the old gentleman's mutilated face, covered with blood, exposing a few old snags of teeth, gurgling and bubbling as he breathed, was not a pretty one. I must have behaved well, however, for Father seemed satisfied. It may be he was trying to test me.

A short time after that Father took me ten miles into the country to drive for him, badly in need of the doze he could get in the buggy on the way. When we arrived at the farmhouse we found that the farmer had a strangulated hernia. An immediate operation was required and there was no other doctor available to give the anaesthetic. So I was pressed into service. The operation went smoothly and I was thrilled and delighted. But now I began to think I was well on the way to becoming a doctor myself. From that day on it was settled. Mother's opposition subsided and finally ceased.

edited by Noah Fabricant, M.D., 1954

Ed. Note: Urling Coe enjoyed a successful practice in Portland, Oregon.

Whatever theory we adopt respecting the foundation of the social union, there is a circle round every human being which no government ought to be permitted to overstep; there is a part of the life of every person of years of discretion within which the individuality of that person ought to reign uncontrolled either by any other individual or by the public collectively. Scarcely any degree of utility short of absolute necessity will justify prohibitory regulation, unless it can also be made to recommend itself to the general conscience. — John Stuart Mill

Grand Rounds

*Ethacrynic Acid, A Potent Diuretic**

M. THOMAS STILLMAN, M.D.
Medical Resident

THE MANAGEMENT OF patients with fluid retention has steadily improved. Probably the largest single factor responsible for this improvement has been the use of increasingly effective diuretics. The four major categories of diuretics which act on renal tubular transport systems are (1) organic mercurials, (2) chloruretic sulfonamides (thiazide derivatives), (3) sulfonamides that inhibit carbonic anhydrase, and (4) aldosterone antagonists. A new chemical class of diuretics was introduced in 1962.¹ This new class was the α and β unsaturated ketone derivatives of aryloxyacetic acid. Structural variations were studied and one of the potent compounds included a chloride substituted aromatic nucleus with a terminal methylene group. This compound is known as ethacrynic acid or MK-595 and is currently produced by Merck Sharp and Dohme under the trade name of Edecrin. This paper will discuss the chemical and pharmacologic aspects of the drug as well as its clinical application in fluid retention in hepatic, cardiovascular, and renal disease.

Absorption, Distribution and Excretion

Ethacrynic acid is chemically unrelated to other diuretic agents. It is sparingly soluble in water but its sodium salt is soluble in water and stable at body pH.² The drug is readily absorbed from the gastrointestinal tract.³ The clearance of ethacrynic acid is dependent upon glomerular filtration rate and both renal tubular secretion and reabsorption. By using C¹⁴-labeled ethacrynic acid in dogs, Beyer and others⁴ show that the drug was transported in the proximal tubules. Secretion occurs in the proximal portion of the nephron with back diffusion in the distal nephron. It

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, August 16, 1966.

Continued

was also shown that secretion was inhibited by Probenicid on a competitive basis and by denitrophenol on a metabolic basis. Intravenous administration of labeled ethacrynic acid in dogs showed 20 to 35% recovery in the urine within 24 hours, and 25 to 50% of the drug recovered in feces within 24 to 48 hours.⁴ Four hours after intravenous injection, 12 to 30% of the dose can be recovered in bile.⁴ Thus the liver is directly involved in the metabolism of ethacrynic acid. Elimination over a seven-day period showed less than 0.5% in exhaled CO₂ and the rest recovered in urine and feces. Thirty to 40% of the drug remains unchanged in the urine; 40% was recovered as ethylacetate and 20 to 30% as a cysteine adduct. Ethacrynic acid is not dialyzable from the tissue.

Mode of Action as a Diuretic

Ethacrynic acid acts directly on the kidneys. On a histochemical basis this drug is similar in action to the mercurial diuretics. Both agents reduce the concentration of stainable protein-bound sulfhydryl groups in renal cells.^{4,5,6,30} It is thought that this reaction interferes with the sulfhydryl catalyzed enzyme systems of the renal cells involved in absorption and secretion of electrolytes leading to a saluresis and diuresis.

Site of Action

There have been a number of studies involving animals and normal individuals in an attempt to demonstrate the diuretic effect of ethacrynic acid and to localize its site of action in the kidney.^{4,7-15,35} Figure 1 will serve as a review of renal physiology needed to understand the mechanism of action of ethacrynic acid. The reabsorption of solute, sodium and chloride occurs in both the proximal and distal portions of the nephron. Proximal reabsorption of solute is accomplished with isosmotic* amounts of water. Approximately two thirds of the filtered sodium and water is reabsorbed in isotonic proportions in the proximal tubule. The remaining filtrate is acted upon distally, two sites being the ascending limb of the loop of Henle and the distal tubule. In the ascending limb sodium is actively reabsorbed in greater proportion to water, entering the medulla to maintain a hypertonic state (counter-current mechanism).¹⁶ Final urine concentration is accomplished by passive movement of free water from the collecting ducts under the control of antidiuretic hormone into the hypertonic medulla. Therefore the ascending limb of the loop of Henle is indirectly involved with the mechanism of final urine concentration. The second site of sodium reabsorption is in the distal tubule. Here sodium may or may not be absorbed isosmotically, but this site is not related to the counter-current mechanism.

Three definitions involving renal hydrodynamics are in order:

1. Osmolar clearance: That volume of water necessary to contain the urinary solutes in a solution isosmotic with plasma.
2. Free water clearance: The excess or deficit of water beyond the osmolar clearance. In a state of water diuresis this value is positive, and during antidiuresis, this value is negative.
3. Free water reabsorption: That volume of reabsorbed solute-free water occurring in the collecting ducts.

A diuretic acting solely on the proximal tubule, inhibiting sodium and chloride reabsorption, during maintained water diuresis, would increase

*See Test Your Word Score Page 521.

urine volume, osmolar clearance and free water clearance. This occurs because of the increased urine flow as well as the increased amount of solute present in the urine to be acted upon by the distal sites of sodium reabsorption. A diuretic acting solely on the distal sites of absorption would produce little change in urine flow, an increase in osmolar clearance, and a decrease in free water clearance under a state of maintained water diuresis. Cannon and others^{7,8} showed that in normal individuals during maintained water diuresis (forced oral and intravenous fluids) ethacrynic acid produced an increase in osmolar clearance and urine volume and a decrease in free water clearance. The authors proposed that the site of action of this drug involved both the proximal and distal sites of sodium and chloride reabsorption, but that the proximal site was more prominent. Goldberg and others⁹ studied the renal hydrodynamics in a similar way but included work involving conditions of hydropenia (withholding fluids), at which time antidiuretic hormone would have its maximal effect. They pointed out that diuretics acting primarily on the proximal tubules would cause an increase in free water reabsorption because of the availability of more osmotically active solute for transport into the medulla, i.e., the ascending limb of the loop of Henle. The authors demonstrated that under the condition of hydropenia, normal individuals showed a decrease in free water reabsorption following ethacrynic acid. After the effects of ethacrynic acid were manifested by a fall in the free water reabsorption, the addition of an osmotic diuretic (Mannitol) did not significantly raise the free water reabsorption. When an increased quantity of sodium was presented to the loop of Henle, active transport into the medulla was blocked. No diuretic before ethacrynic acid has been shown to lower the free water clearance during water diuresis and lower the free water reabsorption during hydropenia. The authors suggest

Fig. 1 — Simplified diagram of the nephron. See text.

*From Gantt, Proceedings of the Symposium, Austin, Texas. The Role of Endocrinology and Diuretics in Hypertension and Edema. Excreta Med Foundation, December, 1965.

Continued

the site of action of this drug to be at the ascending limb of the loop of Henle, a site at which inhibition of sodium and chloride reabsorption would fulfill the above requirements.

Process of Dilution and Concentration

Thus ethacrynic acid has a definite effect on renal processes of dilution and concentration resulting from primarily a sodium and chloride diuresis. Many studies quantitatively demonstrated the marked natriuretic and chloruretic effect of ethacrynic acid. Some studies showed an average maximal effect in natriuresis resulting in excretion of 17% of the filtered sodium.¹² Initially the predominant anion excreted was chloride, and during the first few days the urinary chloride was equal to the sum of the sodium and potassium cations in the urine. Later, the urinary chloride was less than this sum. The urinary volume increase that accompanied this saluresis was quite variable, ranging from 78% to 808% over mean control rates within 15 minutes in normal individuals following intravenous administration of the drug. The diuretic response diminished with continuous administration but was effectively restored by intermittent administration.

Kaluresis

A definite kaluresis occurred with the use of ethacrynic acid. It was most often seen in normal individuals that were salt depleted as well as in the most avid salt retention patients such as the cirrhotics. The loss of potassium is thought to be an indirect result of ethacrynic acid administration. Due to the direct blockage of sodium and chloride reabsorption, potassium is lost through activation of distal sodium-potassium exchange mechanisms because of the increased amount of sodium diverted to this site. Similar results were obtained whether the drug was given orally or intravenously and differed mainly in time of onset.

The saluretic and diuretic effect was dose related to a certain point, after which larger doses failed to induce a significant difference. Table 1 summarizes the diuretic and saluretic effect of ethacrynic acid in eight normal subjects during eight hours following increasing doses of the drug given orally. Maximum sodium excretion occurred with 150 mgm. orally. The diuretic and natriuretic effects reached their peak at about two hours and lasted from six to eight hours following an oral dose.¹⁰

In addition to the excretion of sodium, chloride, and potassium, ethacrynic acid has additional effects. There is a pattern of increased urinary

**Mean of three control studies in each of the 8 subjects.

H⁺, NH₄, and titratable acid with a decreased urinary pH and bicarbonate excretion. Again the explanation given is the activation of distally located sodium-hydrogen exchange mechanisms due to the increased sodium load presented at these sites.

Effect on Aldosterone

Ethacrynic acid increased the secretion and excretion of aldosterone in normal individuals.⁷ It has been shown that aldosterone accelerates the distal sodium-potassium exchange mechanism.¹⁷ This increase in aldosterone secondary to ethacrynic acid has been offered as another explanation for kaluresis during its administration. This was substantiated when ethacrynic acid failed to cause a rise in potassium excretion during natruresis and diuresis in an adrenalectomized subject as well as in a patient on aldosterone antagonists.⁸

Effect on Plasma

Changes in certain plasma constituents following oral ethacrynic acid are summarized in Table 2. There was a reduction in plasma volume as judged by the increase in hematocrit and in the concentrations of urea, plasma proteins, and creatinine. There was a decrease in the plasma chloride and potassium concentrations with a reciprocal increase in the bicarbonate concentration. There was essentially no change in the plasma sodium concentration.

Uric Acid

Ethacrynic acid has been shown to have a similar effect on uric acid as seen with the thiazide diuretics.⁷ During oral administration in lower dosages, there is asymptomatic retention and during intravenous administration or much larger oral dosages, there is an increased clearance of uric acid.

Renal Plasma Flow

The effects of ethacrynic acid on the renal plasma flow are variable, and glomerular filtration rate is little effected by the drug. Of interest is the continued effect of the drug in the presence of reduced glomerular filtration rates. In addition, the state of serum chemistries as well as acid-base states seem to have little effect on the effectiveness of this drug.¹³

Comparison to Other Diuretics in Magnitude and Mode of Action

Ethacrynic acid has been shown to be functionally as well as structurally different from any other class of diuretic agents.^{4,7,9,11,14,18,19,20}

The Chlorothiazides

When compared to the chlorothiazides, both induce a diuresis of sodium, potassium, and chloride but the site of action is different. As with ethacrynic acid, the free water clearance during water diuresis is decreased, but during hydropenia, there is no decrease in the free water reabsorption when chlorothiazide is used.²¹ This suggests an action distal to the loop of Henle, not involving the counter-current mechanism. The natriuretic potency of ethacrynic acid is four to five times that of the thiazides.⁴ The pattern of excretion of the thiazides is that of decreased urinary H⁺, increased urinary pH, NH₃, and bicarbonate concentration and no change in titratable acid. This pattern is opposite from that obtained with ethacrynic acid. The alkalosis obtained with the thiazides results from potassium loss, not loss of urinary H⁺. The thiazides lower the glomerular filtration rate.

The Mercurials

Ethacrynic acid has been compared to the mercurials in potency but has a different site of action. Both drugs have the same histochemical properties, i.e., the binding of sulfhydryl groups in renal cells. The mercurials act primarily on the proximal tubules as shown by increase in free water clearance and free water reabsorption under appropriate conditions. Ethacrynic acid acts more rapidly but for a shorter and more variable period of time when compared to the mercurials.²⁰ Again, it is the rapidity and the site of action, as well as an opposite pattern of H⁺ excretion, that makes this drug different from the carbonic anhydrase and aldosterone inhibitors. Table 3 compares the acute 48-hour weight loss in pounds, employing the maximal effective dosages of the diuretics in clinical use. Functionally it can be said that the difference in ethacrynic acid from the other classes of diuretics lies in its increased potency, rapidity of onset, variability in length of action, and ability to act under any clinical and acid-base state. The fact that this drug is

additive in its action with the other classes of diuretics (especially when used with the carbonic anhydrase inhibitors)⁷ may imply a different mechanism and magnitude of action.

Clinical Application

The Ascites of Cirrhosis

Refractory ascites represents a difficult problem in the management of hepatic cirrhosis. There are many factors that contribute to the accumulation and maintenance of abdominal ascites. These include the renal, adrenal, and cardiovascular factors that play an important role in the retention of salt and water. Shinaberger and Galambos²² list the following adversely modified factors of renal function present in the cirrhotic patient with abdominal ascites.

1. Decreased renal plasma flow.
2. Decreased glomerular filtration rate.
3. Increased proximal tubular reabsorption of sodium and water.
4. Decreased ability to excrete a water load.
5. Increased distal tubular reabsorption of sodium and excretion of potassium under the influence of aldosterone.

Adverse Acid-Base Refractory Ascites

Except for the carbonic anhydrase inhibitors, the other diuretic agents alone or in combination have been effective in therapy. There still remains the group of refractory patients resistant to the usual diuretics. Sherlock and Shaldon²³ and Shinaberger and Galambos²² make the point that the reduced glomerular filtration rate is a major factor in the failure of diuretics in these patients. The development of adverse acid-base states also seems to be a factor contributing to failure. It is on this basis that ethacrynic acid alone or in combination with other diuretics may be

Continued

helpful in the treatment of refractory ascites. Cannon⁷ reported on the use of ethacrynic acid in nine patients with ascites secondary to cirrhosis. All patients were avid sodium retainers, averaging less than 5 mEq. sodium excretion per day. On oral doses of 100 to 200 mgm. per day, the sodium excretion rose from 49 to 437 mEq. per day. Weight loss varied from one-half to 11.5 pounds per day. The electrolyte loss was as reported earlier, and the urinary potassium was higher than in other types of patients treated with the drug.

Four patients were studied on thiazides, mercurials, triamptertine, and spironolactones, and ethacrynic acid was found to be more effective. Lieberman and others²⁴ reported the effects of ethacrynic acid in 32 patients treated over a twelve-month period. All were on a strictly reduced sodium diet. When ethacrynic acid was used with supplemental potassium therapy only, in three patients alkalosis and hypokalemia developed, and two of the three patients went on to a state of hepatic encephalopathy. The dosage of ethacrynic acid was 200 mgm. daily. In eight additional patients in whom a portion of their suggested schedule was used, the effective diuresis occurred as before; but hypokalemic alkalosis developed, and two additional patients developed hepatic encephalopathy. Table 4 illustrates these effects in one of the patients. The authors showed that the alkalosis could occur in the absence of hypokalemia and related the alkalosis to a contraction of the extracellular fluid compartment in the absence of renal loss of bicarbonate.

It can be concluded that the hypochloremic alkalosis and the hypokalemia produced by this potent diuretic may occur as separate electrolyte abnormalities. The authors point out that a simple way of preventing alkalosis is to administer chloride orally in the form of lysine monohydrochloride as a 15% solution. Potassium was supplemented with potassium chloride crystals and the use of spironolactone to decrease the renal loss of potassium. The regimen recommended was as follows²⁴:

1. Lysine monohydrochloride, 25 mEq., q.i.d., on days 1 and 2.
2. Spironolactone (Aldactone-A), 50 mgm., b.i.d., on days 1 and 2.
3. Ethacrynic acid, 100 mgm., b.i.d., on day 3.
4. K Cl, 100 mEq. per day on days 1 and 3, omitted on day 2 to avoid hyperkalemia.

Results

Effective diuresis without significant hypokalemia or alkalosis was obtained in 23 out of 32 patients. Ethacrynic acid should be started at a lower dose and increased to the recommended dose if needed.

Chronic Congestive Heart Failure

The use of ethacrynic acid in patients with fluid retention secondary to chronic congestive heart failure has been reported.^{7,11,20,25} Cannon and others⁷ reported on 14 patients with long-standing congestive heart failure, the majority secondary to arteriosclerotic heart disease. The average sodium loss in the urine for this group of patients was 11 mEq. per day. In the dosage range of 100 to 200 mgm. of ethacrynic acid daily, the rate of excretion rose from 51 to 734 mEq. per day. An effective weight loss was obtained, but all developed hypochloremic alkalosis as treatment continued. There was an associated mild hypokalemia.

A study following two years of experience was reported by Cannon and others.⁸ In a group of 30 patients with chronic congestive heart failure treated over a two-year period, effective mobilization of edema fluid was obtained in 17. The diuretic response diminished with continuous therapy but was effectively restored by intermittent therapy. The better results seem to be in those patients treated for a short period to obtain a rapid mobilization of retained fluid. Daley²⁰ reported on five patients treated with 150 mgm. of ethacrynic acid orally for five days. All patients diuresed, the amount varying with the magnitude of edema present. The diuresis started in one hour, reached a maximum effect in two hours, and maintained a basal level after eight hours. No significant changes in serum electrolytes were reported. Sperber²⁵ reported on 27 patients with congestive heart failure treated over an average period of four months. The authors make the point that the dose must be individualized but that the dosage most often used was 50 mgm. b.i.d. They reported a good response in 80% of the patients. A point that these authors make is that this drug has the ability to reverse a positive sodium balance in the avid sodium retainer when faced with a salt load. Ethacrynic acid provides a measure of protection for the patient who does not adhere to a prescribed low sodium diet.

Acute Pulmonary Edema

In view of its potent diuretic action, the efficacy of long-term use of ethacrynic acid in the cardiac patient remains questionable. However, its properties as a diuretic have encouraged its use in the management of acute pulmonary edema.^{26,27,28} The effect of intravenous ethacrynic acid is seen within minutes and its maximum diuretic activity occurs within 30 minutes. Due to the decrease in cardiac output and resulting reduction in glomerular filtration rate in patients with acute pulmonary edema, other diuretics often give poor results. Fine and Levy²⁸ reported effective results in five patients with acute pulmonary edema given 50 mgm. of ethacrynic acid intravenously along with the usual therapy (not including any other diuretic). The excretion rates of electrolytes were as follows:

Na — 232 microequivalents to 1463 u eq/min.

Cl — 315 microequivalents to 1455 u eq/min.

K — 48 microequivalents to 155 u eq/min.

An average of 600 ml. of urine was lost in a two-hour interval. Rosenberg²⁶ reported good results in 15 patients treated for acute pulmonary edema with 50 mgm. of intravenous ethacrynic acid on admission. The second case summary exemplifies the rapid and potent diuresis with excellent results in the treatment of acute pulmonary edema. Rapid phlebotomy is still the preferred direct approach to a rapidly decreasing venous pooling of blood from the right side of the heart. The use of ethacrynic acid represents a more indirect approach of clearing pulmonary edema by renal excretion of salt and water. In the anemic or hypotensive patient, the rapid diuresis provided by this drug may be essential in the treatment of pulmonary edema. An additional usage of this drug was reported by Ledingham,²⁷ who suggested the prophylactic

Continued

use of 12.5 to 50 mgm. of ethacrynic acid added to each unit of blood prior to transfusion. In the severely anemic patients complicated by fluid retention, the chances of precipitation of pulmonary edema during transfusion are reduced. He reported seven such patients without complication.

Refractory Edema of Renal Disease

The use of ethacrynic acid in the treatment of refractory edema associated with renal disease has also been reported. Hagedorn and others²⁹ noted short-term success in patients with the nephrotic syndrome. Six patients with kidney disease (five out of six biopsy-proven) while on a controlled protein diet, marked sodium restriction, and fluids ad lib., were treated with 100 to 200 mgm. of ethacrynic acid daily. All showed diuresis with weight loss within 24 hours, the maximum decrease in weight and disappearance of edema occurring by the 10th day of therapy. In seven to ten days the sodium and chloride excretion returned to previous control values, and this signaled the completion of the diuretic response. Initially, the potassium excretion increased but not significantly over an extended period of therapy. Maher and Schreiner¹³ treated 30 patients with renal disease. Ethacrynic acid was extremely effective at very low glomerular filtration rates as low as 20 liters/24 hr. and its effect was dose-related. No other diuretic singly or in combination achieved the diuresis equal to that produced by this drug. These authors noted the successful diuresis in a patient with ischemic oliguria with impending tubular necrosis following an episode of hypotension. Mannitol and hydration failed to increase urinary output, while 100 mgm. of ethacrynic acid had good effect. In the patient with circulatory overload the use of a blockade diuretic would be preferred over an osmotically active agent such as Mannitol.

Side Effects

Gastrointestinal Disturbances

A drug as potent as ethacrynic acid has side effects and undesirable results if not carefully monitored during therapy. Gastrointestinal disturbances make up a good part of reported toxic reactions, including nausea, vomiting, and diarrhea.^{2,13,29} Other reactions reported could

not be definitely attributed to this drug alone or were inconsistent. Table 5 includes a list of reactions in a study of 38 patients treated with ethacrynic acid.¹³

Electrolyte Acid-Base Disturbances

Undoubtedly the most dangerous toxic effect is the potential electrolyte and acid-base disturbance. The common disorders that develop are a severe hypokalemia and a hypochloremic alkalosis. Hyponatremia does not seem to be a significant problem. Cannon and others³² describe a phenomenon referred to as "contraction" alkalosis following diuresis with ethacrynic acid. This acid-base disturbance results from a significant rapid contraction of the extracellular fluid space following saluresis and diuresis. Since the urinary losses of bicarbonate during diuresis are negligible, the extracellular space contracts around the initial bicarbonate pool. The alkalosis results from this increased bicarbonate concentration.

The situation tends to potentiate itself upon continued usage of the drug due to the continued loss of H⁺ with the returning of additional amounts of new bicarbonate to the extracellular fluid. The kidney is unable to compensate by bicarbonate excretion, for it is stimulated to retain sodium and is presented with a glomerular filtrate relatively poor in chloride. This enhances persistent H⁺ excretion and bicarbonate reabsorption. As was pointed out by Lieberman and Reynolds,²⁴ such a disturbance cannot be corrected unless supplementary chloride as well as potassium is provided during therapy.

Other Disturbances

In the cirrhotic patient the electrolyte disturbance may precipitate *hepatic encephalopathy*.^{7,24} In the cardiac patient who is on digitalis, the loss of potassium, especially over a short period of time as in the treatment of acute pulmonary edema, represents a real danger in developing *digitalis toxicity*. Careful monitoring along with potassium replacement is essential during treatment.

Dixon and others³³ demonstrated the increased ethanol toxicity in mice while on ethacrynic acid. The authors proposed a block by this drug in the formation of acetaldehyde from ethanol and possible serious consequences of alcohol taken during treatment with ethacrynic acid.

Various authors have mentioned *blood dyscrasias* that may be associated with the use of ethacrynic acid.^{2,5,23,34} These include granulocytopenia, thrombocytopenia, and thromboembolic phenomena. Usually the patients were on other drugs that could also be implicated. In our third Case Summary, the patient showed definite bone-marrow depression following the use of ethacrynic acid, but since other drugs were also being used, it is difficult to determine which drug induced depression.

Summary

The management of acute and chronic fluid retention has improved with the development of effective diuretics for both intravenous and oral usage. Ethacrynic acid, a derivative of aryloxyacetic acid, represents a new class of diuretic agents. The drug is transported in the proximal

Continued

portion of the nephron for its direct action within the kidney. It is thought that ethacrynic acid interferes with the sulfhydryl catalyzed enzyme systems within the renal cells. The liver is directly involved in its metabolism and the drug is excreted in the urine and feces. Through renal clearance studies it has been shown that the probable primary site of action within the kidney is the ascending limb of the loop of Henle. Ethacrynic acid causes a direct saluresis of sodium and chloride with a secondary indirect loss of potassium and hydrogen ions. A large concurrent diuresis occurs with the above saluresis. Initial action is seen in minutes following intravenous administration, with a maximal effect in 30 minutes and a duration of action of about two hours. Its potency, rapidity of action, and ability to work under adverse acid-base conditions, as well as its mechanism of action differentiate this drug from other diuretics.

Ethacrynic acid has proven effective when all other diuretics have failed and also has an additive effect when used in conjunction with other diuretics. The dosage of ethacrynic acid must be individualized in clinical usage. Its rapid effect has been especially useful in the treatment of acute pulmonary edema. The most serious side effects result from the electrolyte imbalance following diuresis. The conditions reported are hypokalemia and hypochloremic alkalosis called a contraction alkalosis. This is explained by a reduction in the extracellular fluid space with concomitant renal retention of bicarbonate resulting in an increased bicarbonate concentration. Concurrent administration of potassium and chloride is strongly recommended during ethacrynic acid therapy. Other side effects include gastrointestinal disturbances, asymptomatic uric acid retention, and possible blood dyscrasias.

Case History

Case 1

A 54-year-old white male, with a history of heavy alcohol intake for 30 years, first developed abdominal ascites in February of 1965, at which time he was placed on oral diuretics by his private physician. The patient was referred to Hennepin County General Hospital in November of 1965 and was hospitalized for evaluation of refractory abdominal ascites. On physical examination he had many of the stigmata of Laennec's cirrhosis, including massive abdominal ascites, mild jaundice, wasting of musculature of the shoulder girdle, sparse body hair, spider nevi of the face, neck and chest, and palmar erythema. A liver biopsy confirmed the diagnosis of Laennec's cirrhosis. Attempt at diuresis with mercurials, thiazides, triamterene, and spironolactone was unsuccessful. A regimen using ethacrynic acid as suggested by Lieberman and Reynolds was initiated with excellent results. The patient showed a saluresis with diuresis of 30 pounds over approximately 28 days. He was maintained on a one-gram sodium diet with fluid restriction in the range of 1,000 cc. per day. The patient had no remarkable side effects during treatment. He was discharged and is being followed on the ethacrynic acid regimen in the Outpatient Department.

Case 2

A 51-year-old white male had a history of rheumatic heart disease. There were symptoms in the past suggestive of congestive heart failure, but he was never treated. Five days prior to admission he noted progressive exertional dyspnea with orthopnea and ankle edema. On the night of admission he developed acute respiratory distress and was admitted for treatment of acute pulmonary edema. The patient was critically ill with a blood pressure of 90/0, a pulse of 130 and a respiratory rate of 40. There was marked central and peripheral cyanosis, and central venous pressure measured 34 cm. H₂O. He was given 50 mgm. of ethacrynic acid I. V. along with initial therapy of rotating tourniquets, aminophiline, and digitalization. An immediate diuresis was obtained, and total urine output for the first 24 hours was 4,000 cc.

ETHACRYNIC ACID

The breakdown of urine output during the first 24 hours is shown in the table below. The patient was asymptomatic in 12 hours and had an uneventful hospital course.

	Time	Urine Vol.	Sp. Grav.	
Ethacrynic acid, 50 mgm. I. V.	2:00 a.m.	—	—	Na 133, K 6.2, CO ₂ 14, Cl 89, BUN 28
	4:00 a.m.	2,000	1.005	
	8:00 a.m.	950	1.004	Na 130, K 4.8, CO ₂ 17, Cl 91, BUN 28
	12:00 noon	425	1.008	
	4:00 p.m.	225	1.012	
	8:00 p.m.	250	1.013	
	12:00 a.m.	175	1.018	

Case 3

A 61-year-old woman who was a known alcoholic was admitted with abdominal ascites and bilateral pleural effusions. She was placed on thiazide and triamptere therapy. Since little diuresis occurred, ethacrynic acid was added with good results. Approximately four days after this drug was added, a pancytopenia occurred. A bone marrow was compatible with a toxic depression, probably drug-induced. The patient went on to die due to complications related to her hepatic disease.

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Leaders are persons with loud voices, long arms and legs, active elbows, and a determination to stay in front. — Nuggets

This pain is getting on my nerves.

Patients in pain often experience concomitant anxiety and tension, which may add to the burden of pain.

For such patients, you may want to prescribe a preparation that offers more than simple analgesia.

A good choice is often EQUAGESIC® (meprobamate and ethoheptazine citrate with aspirin). It helps relieve pain. And anxiety. And skeletal muscle spasm as related to pain or anxiety and tension.

Equagesic® TABLETS (meprobamate and ethoheptazine citrate with aspirin)

Precautions: Keep out of reach of children. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. Withdraw gradually after prolonged high dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance. If drowsiness, ataxia or visual disturbances occur, reduce dose. If symptoms persist, caution patients against operating machinery or driving. Give cautiously to patients with suicidal tendencies. Treat attempted suicide with immediate gastric lavage and appropriate supportive therapy.

Side Effects: Ethoheptazine and aspirin may occasionally cause nausea, vomiting, epigastric distress, and rarely dizziness and CNS depression. Overdosage may result in salicylate intoxication. Meprobamate rarely causes allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioedema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Rarely, cases of aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported; almost always, in the presence of known toxic agents.

Contraindications: History of sensitivity or severe intolerance to aspirin or meprobamate.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Parepectolin for quick relief of acute diarrhea
... soothes colicky pain with paregoric*
... consolidates fluid stools with pectin
... adsorbs irritants with kaolin,
and protects intestinal mucosa

Whether it's a 24-hour "bug", a food problem,
or simply nervousness and anxiety, Parepectolin
will bring the diarrhea under control until etiolo-
gy can be determined. In some cases, Parepec-
tolin may be all the therapy necessary.

Parepectolin®

Each fluid ounce of creamy white suspension contains:

*Paregoric (equivalent) (1.0 dram) 3.7 ml.
Contains opium ($\frac{1}{4}$ grain) 15 mg. per fluid
ounce.

warning: may be habit forming

Pectin (2½ grains) 162 mg.
Kaolin (specially purified) . . . (85 grains) 5.5 Gm.
(alcohol 0.69%)

Usual Adult Dose: One or two tablespoonfuls three
times daily.

Usual Children's Dose: One or two teaspoonfuls three
times daily.

WILLIAM H. RORER, INC.
Fort Washington, Pa.

Tandearil® oxyphenbutazone

Therapeutic Effects: Tandearil is a nonhormonal compound which may rapidly resolve inflammation and help restore normal joint function. Its action does not affect pituitary-adrenal function or impair immune responses. Its value in osteoarthritis is especially noteworthy because this disorder responds inconsistently to steroids and is often resistant to salicylates. Further, indomethacin is limited only to osteoarthritis of the hip, whereas oxyphenbutazone is effective in all forms of the disease.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage. Make regular blood counts. Discontinue the drug and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: The initial daily dosage in adults is 300-600 mg. in divided daily doses. When improvement occurs, dosage should be decreased to the minimum effective level; this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

For complete details, please refer to full prescribing information. 6562-VI(B)R

Life Insurance Settlement Options

In addition to the company from whom you purchase and the type of life insurance contract that you purchase, the method of settlement of the proceeds is of major importance.

Following is a brief summary of the various options available on most policies today. Proper selection of the right combination of options is almost as important as having an adequate amount of insurance.

The Lump-Sum Option: This is self-explanatory. It should be used primarily to provide needed cash immediately, when this cash is not available from other sources.

The Interest Option: The company retains the proceeds and pays a stipulated rate of interest on them. Usually the right to withdraw the proceeds in part, or in total, is vested in the beneficiary. This option is beneficial when income, or cash, is not needed immediately but will be later. This option can be changed to another at a stipulated time or at the beneficiary's discretion.

Income for a Fixed Period: This pays income for a pre-determined fixed period. The amount of income is governed by the period elected and the proceeds available. The most common use for this option is to provide a monthly income for the wife during the dependency period of the children.

Income of a Fixed Amount: This pays income at a certain stipulated rate until the proceeds are exhausted. The number of installments is governed by the proceeds in the company's hands and the stipulated rate of interest. This option is most commonly used where a fixed rate of income is more important than the period for which it is paid.

The Life Income Option: This option provides a stated income to the beneficiary for as long as he, or she, lives. The amount of the income payment for each \$1,000 of proceeds depends upon the number of minimum guaranteed payments (5, 10 or 20 years), the age and the sex of the beneficiary.

Subject to stated minimums, the period of payment under any of these options may be annually, semi-annually, quarterly or monthly.

In addition to these options, the proceeds of an insurance policy may be settled by nearly any combination of options. For example, on a \$12,000 policy, it would be possible to have \$2,000 of the proceeds paid in cash, \$5,000 of the proceeds retained at interest until a stated date, and then paid as a life income with payments guaranteed for five years, \$2,000 paid out in installments for a fixed period of five years, \$1,000 paid out at the rate of \$50 per month until exhausted, and the remaining \$2,000 paid as a life income with payments guaranteed for twenty years. This example illustrates the use of six options on one policy. While such a settlement would be uncommon, it demonstrates the flexibility of planning available through proper use of settlement options.

Settlement options which best fit your individual programs should be utilized. These options are necessarily subject to change with your needs. Your choice of options must be governed by family needs, beneficiaries' ages, and also by your general estate plan provisions. For this reason, your insurance counselor and your attorney should both review your options in order to insure accomplishment of your goals without adversely affecting your estate plan.

Anatomy Dissection

Until probably sometime during the thirteenth century, the anatomy that was taught to students of medicine was entirely of a theoretical nature, and what was worse, the theories themselves were often quite erroneous. It is believed that the practice of dissection of human bodies for classes in anatomy was started very likely sometime during the thirteenth century. However, it was not until several hundreds of years later that the student did any dissection himself. And even then there were often only two bodies to be dissected in a medical school during a school year. In the early days, the teacher lectured while sitting at his desk as a barber did the dissecting, and a demonstrator pointed out the various structures with a wand. It actually was a couple hundred years before the teacher had acquired enough energy to get off of his fanny and stand beside the cadaver to point out the structures himself.

Prophecy

Don't ever prophesy; for if you prophesy wrong, nobody will forget it; and if you prophesy right, nobody will remember it. — Josh Billings

The owl is therefore the bird of wisdom, because even a fool can see when it is light; it is the wise man that can see when it is dark. — Panin

Abstracts, Briefs and Commentaries

LATE DEVELOPMENT OF PRIMARY CARCINOMA OF THE COLON FOLLOWING URETEROSIGMOIDOSTOMY

This interesting article by members of the departments of Surgery and Pathology of the University of Minnesota is instructive. It represents an extensive review of records and various methods of treatment in a very trying situation. Methods of ureteral diversion date back to 1851 in London. The authors quote Hinman, who in 1936 stated that more than 1,000 techniques had been developed and tried. In 1952 Bricker reported results using ileal segments as substitutes for the urinary bladder. This technique has almost completely replaced the use of ureteral sigmoidostomies for ureteral diversion of urine. However, there are a large number of people still living with modifications of ureterosigmoidostomies.

Seventy-seven bilateral ureteral sigmoidostomies have been performed at the University Hospitals. Ages of patients ranged from four months to 84 years. Of 83 patients, 61 are dead. There were 23 patients who survived 10 years or more; 15 are known to be alive now. Of the 23 patients that survived more than 10 years, two developed proved carcinoma of the colon at the site of the implant. A third patient is reported in great detail. This patient was first admitted in 1945 at age 21, with a 12-year history of chronic interstitial cystitis. She was readmitted in 1948 and bilateral ureterosigmoidostomy was done. She was then readmitted on nine occasions for various complications with hydronephrosis, fever, pain, blood changes, etc. In 1964 a right nephrectomy was performed. In 1965 she developed critical sigmoid obstruction, (17 years after ureterosigmoidostomy) and a double-barrel colostomy was done. She was discharged to return for a sigmoid resection in four weeks. This was done by resection and end-to-end anastomosis.

Pathological study of the removed segment revealed a tumor completely surrounding the ureteral anastomosis. Microscopic sections revealed undifferentiated carcinoma.

Conclusions drawn were that this type of urinary diversion may be associated with an increased risk for development of carcinoma of the colon. Patients having such a procedure should be followed throughout their lives by barium enemas and proctoscopic examinations.

Continued

COMMENT: The authors should be complimented on the excellence of this publication and the care given this patient. The magnitude of this patient's hospital care extending over many years, together with unlimited examinations and operations, would practically preclude the use of a private hospital unless the patient had unlimited insurance coverage. I can highly recommend a review of this original publication for full details.

Urdaneta, Luis F., Duffell, David, Crury, C. D., and Aust, J. Bradley: Ann Surg, September, 1966.

MAJOR THORACIC SURGERY AFTER SIXTY

The author reviewed the mortality and morbidity of 340 major thoracic operations in 338 patients ranging in age between 60 and 90 years. The majority of the procedures were for pulmonary lesions. There were no intra-cardiac procedures (7 pacemaker implantations). Of the 338 patients, 186 had some other type of concomitant disease or remote organ involvement by neoplasm. Complicating heart and lung disease became more prominent in the older age group.

Complications were avoided by complementary tracheostomy, empirical preoperative digitalis administration in patients with borderline cardiac reserve, and positive pressure therapy in individuals with pulmonary insufficiency.

There were postoperative complications in 33 patients. Of these, 25 involved the cardiovascular and pulmonary systems. The overall mortality in 338 patients was 3.83% (13 deaths). Interestingly, all deaths occurred in patients below 73 years (19 patients over this age survived without mortality).

COMMENT: This interesting series is heartening. Another report had recorded the postoperative mortality as considerably higher (10-25%) in this same age group with similar lesions.

PATENT DUCTUS ARTERIOSUS

The authors of this article review 100 consecutive patients with patent ductus arteriosus treated at the University of Mississippi Medical Center, Jackson, Mississippi. All were treated operatively. There was not a single mortality in the correction of the isolated lesion of patent ductus arteriosus. The authors attribute this brilliant result to successful management of a wide variety of operative and postoperative complications, including hypertensive reaction, pulmonary complications, wound infections, vocal cord paralysis, thoracic duct fistula, and heart failure.

Hardy, James D., Webb, Watts R., Timmis, Hilary, Watson, David G., Blake, Thomas M.: Patent Ductus Arteriosus. Ann Surg 164:5:877, 1966.

THE MYCOPLASMA MYSTERY

In the past, doctors classified nonbacterial pneumonias as "atypical pneumonias." They split the atypical pneumonias into two groups: those without and those with cold agglutinins. The "without" group included those associated with an identifiable cause: ornithosis, Q fever, histoplasmosis. But the "withs" resisted classification and were lumped together under the convenient name "primary atypical pneumonia." Then the lump began to break up.

Virologists scoured the respiratory tree and found a host of possible causes. Among these was an atypical virus called "Eaton Agent." But was "Eaton Agent" a true virus? No, it turned out to be an atypical bacterium — a pleuropneumonia-like organism (PPLO) — in disguise.

In the course of these events the name of the disease was dutifully changed from "primary atypical pneumonia" to "Eaton Agent Pneumonia" to "pleuropneumonia-like pneumonia." The name-calling was not yet over. Bacteriologists had the last word. They pointed out that the PPLO was really a bacterium of the genus mycoplasma. Why not call the disease "Pneumonia due to Mycoplasma Pneumonia?" And so it rests.

Alexander and his co-authors studied the incidence of pneumonia in patients in a large cooperative medical group in Seattle. They observed 1051 cases of pneumonia, an annual rate of 12.9 per 1,000.

The incidence of clinically-recognized pneumonia due to mycoplasma pneumonia was between 1 and 1.5 persons per 1,000. The pneumonia occurred most frequently in children and adolescents and had no seasonal correlation. Patients suffered from headache and fever, but almost none were hospitalized. They complained of upper-respiratory-tract problems more often than in other types of pneumonia, and more often showed white-count elevations. The physicians who saw the patients were usually right when they diagnosed the pneumonias as "atypical" or "viral."

MALLORY-WEISS SYNDROME

Review of 20 Cases and Literature Review

Major Holmes reviews 20 cases of Mallory-Weiss syndrome (severe gastrointestinal bleeding from spontaneous mucosal laceration of the esophagus) seen at the Brooke General Hospital in the past 3½ years. This represents 5% of all upper gastrointestinal bleeders seen. Clinical management included emergency esophagoscopy, gastroscopy, and upper gastrointestinal x-rays in all patients with upper gastrointestinal bleeding. Eight patients required surgery in which the mucosal laceration was sutured through a generous gastrotomy incision. The features of Mallory-Weiss syndrome include alcoholic debauch, persistent nausea, vomiting and wrenching followed by massive upper gastrointestinal hemorrhage. These findings were exhibited in the majority of cases reviewed in this article.

Continued

The author suggests that Mallory-Weiss syndrome may be considerably more frequent than current medical literature would indicate and recommended vigorous diagnostic measures in the management of the acute upper gastrointestinal bleeder.

LATE RESULTS OF BRONCHIAL RECONSTRUCTION

Rupture of a major bronchus is an uncommon complication of thoracic trauma. Early recognition and treatment, however, are of utmost importance in preserving functioning pulmonary tissue. Current techniques of bronchial repair permit satisfactory anatomical and function reconstruction of injured bronchi. Long-term results have been gratifying.

Theodore A. Peterson, M.D.
Minneapolis, Minnesota

Ahrari, H., Ekestrom, S. Stockholm, Sweden: Late Results of Bronchial Reconstruction. Ann Surg 164:5:859, 1966.

INTERMITTENT CLAUDICATION

In 198 cases of uncomplicated intermittent claudication followed for five to 12 years or to death, the over-all mortality was 46.5 percent; the mortality at five years was 25 percent. Most of the deaths were due to cardiovascular disease, with myocardial infarction occurring as the commonest lesion.

Age did not affect the prognosis, apart from the fact that older patients have reduced life expectancy in any event. The prognosis was not much affected by the duration of the disease when first seen, whether it was unilateral or bilateral, or the level of the occlusion. Hypertension and pre-existing ischemic heart disease had a harmful effect.

The outlook for the affected limbs was good. In most of the survivors the claudication was either improved or unchanged, but many were disabled by cardiac or cerebral vascular disease. The over-all amputation rate was 7.1 percent and the rate in survivors 6.6 percent. In 69 cases a lumbar sympathectomy was done, chiefly for ischemic changes in the feet. Some benefited from the operation.

Claudication indicates atherosclerosis, usually generalized; this fact is emphasized when the ten-year survival rate is compared with that of patients who had angina or survived a myocardial infarction, for the results are similar. Treatment, whether medical or surgical, should be assessed in the light of these observations.

Take Your Choice

At each minute we are obliterated by the idea and the sensation of time. And there are only two ways of escape from this nightmare, of forgetting it: pleasure and work. Pleasure anuses us. Work fortifies us. Let us choose. — Baudelaire

Book Reviews

The whole object of education is, or should be, to develop mind. The mind should be a thing that works. It should be able to pass judgment on events as they arise, make decisions. — Sherwood Anderson

**DIE ARTHROSIS DEFORMANS DES KNEIGEL-
ENKES** — Walter Mohing, Springer-Verlag Berlin
Heidelberg New York 1966.

The need of a uniform classification of joint disease becomes immediately apparent when one takes up the first task of simply translating the title of this book. Literally it is "The Deforming Arthrosis of The Knee Joints." The term arthrosis is not used much in the English literature and most would be inclined to translate this as degenerative arthritis or osteoarthritis of the knee. Nevertheless this is an excellent 212-page treatise dealing with degenerative arthritis of the knee from the point of view of the influence of static-mechanical factors in the cause, progression, and localization of knee joint changes. The author is an orthopedist and he bases his text on a personal experience of 2000 cases.

There is an introductory chapter on anatomy and the mechanics of knee joint motion. The major portion of the text deals in considerable detail with individual entities that have caused a secondary arthritis, such as congenital disorders, post-traumatic disorders, obesity, and patellar pathology. There are numerous and excellent photographs and x-rays throughout. The chapter on treatment is brief but to the point. There is an extensive bibliography referring primarily to the German literature which includes the year 1963. The book will be primarily of interest to orthopedists, rheumatologists, and physiatrists, although other physicians with a knowledge of German should be able to gather some useful information from the text.

PATHOLOGY — 5th Edition, 2 Volumes, edited by
W. A. D. Anderson, 1,439 pages, 1,267 illustrations.
C. V. Mosby Company, St. Louis, Missouri, 1966.
\$21.00.

PATHOLOGY made its debut in 1948. Because of the skills of its knowledge broker, editor W. A. D. Anderson, it quickly became the premier bluechip textbook of pathology. He carefully picked his contributors, diligently compressed their prose and kept his eye on the fact market. As information expanded, the book grew. By its fourth edition in

1961, it weighed an unwieldy nine pounds. Anderson, always alert to the needs of his readers, has solved the problem by carrying out a 2:1 split.

The two volumes making up the fifth edition are organized similarly to its single-volume predecessor. Thirty-nine contributors present a systematic, comprehensive, and balanced organ system review. The descriptions are condensed, the photomicrographs clear, and the references apt. According to the preface, the purpose of the book is to satisfy the whims of beginners, pedagogues and practitioners. This is an impossible task. Such a trio will find nits to pick in any book, especially a fundamental text that attempts to blanket a sprawling field. But I think Anderson has come close to his goal. In my opinion, the divided *Anderson* still stands several notches above its competitors.

MODERN TREATMENT — Treatment of Gastro-
intestinal Infections; Treatment of Superinfections.
Edited by Marcel Patterson and Harold J. Simon.
Harper and Row, New York, 1966.

MODERN TREATMENT is published as a bimonthly paperback volume, each number considering one or two fields of medicine. Patterson, editing the gastrointestinal portion, notes that these infections have become uncommon in this country because of painstaking work in the food industry and public health.

However, the occasional breakdown in sanitation still poses a considerable threat of intestinal disease. The increasing urbanization of population means that sanitation failures can result in massive epidemics.

Advances have been in control rather than therapy of disease. Potential for serious gastrointestinal infection is constant. In this day of instant travel with the entire earth no more than twelve hours away from any airport, we can no longer comfortably assume that exotic diseases, particularly gastrointestinal infestations, will not present themselves locally.

The discussion edited by Simon concerns opportunistic infections. These are the ever menacing factors that complicate all phases of surgery.

Reuben Berman, M.D.
Minneapolis, Minnesota

He doesn't feel he "suffers" from hypertension

**Butiserpazide® lowers blood pressure
so smoothly that patients are often untroubled
by either disease *or* therapy**

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure¹...at times to levels *below* those attained with previous therapy²; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness²; plus

(3) "...lowered incidence of drug side effects."²

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 25 mg. (¾ gr.); Reserpine 0.1 mg.

Butiserpazide®-50

Prestabs®* Tablets

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

*15 mg. of Butisol (butabarbital), plus the other ingredients, in outer layer; 15 mg. of Butisol (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with anti-hypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyper-

uricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †Warning: May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: Penna. M. J.: 67:35, 1964. 2. Coodley, E. L.: Curr. Ther. Res. 4:460, 1962.

WANTED — Internist, board certified or qualified, to associate with two board certified internists. Ten man multi-specialty group. (Lenont Peterson Clinic, Virginia, Minnesota) — Heart of the expanding taconite industry.

PHYSICIANS WANTED: Internist, downtown Minneapolis, rapidly growing, uniquely transferable practice. Guarantee commensurate with experience, good percentage from start, prompt partnership. Send resumé, including income desired to Box B, Room 1153, Plymouth Building, Minneapolis, Minnesota 55402.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE — 365; 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTITIONER — to join established five-man group consisting of three general practitioners, a general surgeon, and an internist. Excellent clinic facilities situated adjacent to the city hospital. Starting salary negotiable. Retirement plan and many other fringe benefits. Call or write: Richard F. Lehigh, Owatonna Clinic, Owatonna, Minnesota 55060. Phone: 451-1120.

EXCELLENT OPPORTUNITY for Intern or Resident finishing in June or July to try practice in specialty group on locum tenens basis — June 1 thru August 31, 1967. Replacing Internist on leave of absence. Option of remaining on staff if desired. Salary open. Write or call collect, 281-3184, Northwestern Clinic, Crookston, Minnesota.

GENERAL PRACTITIONER wanted by two-man general practice group. Surgery within capability. Community Hospital. Eligible partnership if preferred. Write: MINNESOTA MEDICINE — 393, 496 Lowry Medical Arts Building, St. Paul — 55102.

CLASSIFIED ADVERTISEMENTS

RESIDENTS IN PSYCHIATRY — Opening for July 1, 1967. Stipend \$11,400 for physicians just completing internship. Federal stipend of \$12,000 annually with an extra \$3600 tax exemption available to physicians with 4 years non-psychiatric training or experience following internship. Graduates of American schools must be eligible for Iowa licensure. Foreign graduates must have ECFMG certificate. This is an acute treatment hospital with 450 in-patients and large outpatient department, children's unit under direction of Board-certified Child Psychiatrist. Intensive didactic teaching program with rich clinical experience directed toward preparing the resident for Board certification. Thirteen senior staff members including ten Board certified. Numerous consultants authorized for 18 residents. Affiliation with University of Iowa. Enthusiastic training and treatment programs that are best appreciated by a personal visit. Write W. C. Brinegar, M.D., Superintendent or John J. Worthington, M.D., Director of Psychiatric Training, Mental Health Institute, Cherokee, Iowa 51012.

EXPANDING, UPPER MIDWEST, Multispecialty group; college city, seeks the addition of: Internist, Otolaryngologist, General Surgeon, Radiologist, and Urologist. Unlimited income. Contact: John J. Eustermann, M.D., c/o Mankato Clinic, Ltd., Mankato, Minnesota 561-387-1811.

AVAILABLE for immediate occupancy, modern doctors' offices in the Midway Medical Arts Building, University and Snelling Avenues, St. Paul. A choice Midway location near the new Inter-City Freeway with excellent public transportation available and adequate parking. Contact: Cal Douglas or Len Loftus at 646-7578-St. Paul or write Harold J. Slawik Properties, Inc., 1850 University Avenue, St. Paul.

PHYSICIAN interested in internal medicine wanted for Medical Service. Starting salary \$12,873 to \$17,221, depending on qualifications. Liberal fringe benefits. Non-discrimination in employment. Contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa.

WANTED—Locum Tenens, Summer, 1967, June, July and August. Board eligible in internal medicine. University trained. Write: MINNESOTA MEDICINE — 374, 496 Lowry Medical Arts Building, St. Paul 55102.

PSYCHIATRY RESIDENCY POSITIONS AVAILABLE: July 1967 for three-year accredited program. A dynamically oriented broadly-based well-balanced opportunity for sound training. Meadowbrook Hospital is Nassau County General Hospital and is centrally located in the most desirable and beautiful area in the country. Easy commuting distance to New York City. 3000 inpatient psychiatric admissions per year. 24-hour walk-in clinic and all psychiatric modalities. Abraham S. Lenzner, M.D., Director, Psychiatric Education, Meadowbrook Hospital, P.O. Box 175, East Meadow, Long Island, New York 11554.

FOR RENT: Modern suburban office space now available, with large private parking area, on South Robert near Signal Hills. Successfully occupied by doctors for last twenty-five years. Newly remodeled. Reasonable Rent. 950 South Robert. Telephone: 224-7913, St. Paul.

WANTED: General practitioner for local tenens in Lake District two weeks in April and two weeks in June — Call 474-6227.

WANTED: GP to take over practice due to health. Equipment and all available with good financing. Northwest Suburban Minneapolis. Call or write: Bernard S. Nauth, M.D., 6120 Osseo Road, Minneapolis, Minnesota 55429. Phone: 561-4390 or residence 929-0958.

GENERAL PRACTITIONER wanted to join well established practitioner. Located 65 miles north of Minneapolis-St. Paul area. Population over 3,000. Hospital in town. Good schools, churches, and fine fishing and recreational area. Contact: A. C. Peterson, M.D., 200 E. Forest St., Mora, Minnesota 55051.

WANTED INTERNIST for local tenens in Lake District two weeks in April and two weeks in June. Call 474-6227.

ST. CROIX VALLEY luxury homes in spectacular locations. Great for your whole family and you. Spring Company. Call or write Harold Onstad Marine on St. Croix 612-663-8261.

BEAUTIFUL NEW OFFICE available now for second office or solo practice. Wonderful opportunity, progressive area, only specialists in area now are OB-GYN. Excellent lease arrangement! Write: MINNESOTA MEDICINE — 375; 496 Lowry Medical Arts Bldg., St. Paul 55102.

GENERAL PRACTITIONER, associate wanted to join 34-year-old solo GP in a not excessively active family practice in a N.E. suburb of Minneapolis. Modern office with complete x-ray and lab facilities, 15 min. from a large hospital with affiliated nursing school and residency program all fully accredited, 20 minutes from the University of Minnesota and the downtown area. Gary Good, M.D., 3827 Central Avenue N.E., Minneapolis 55421. Write or call collect 613-788-9091.

PHYSICAL MEDICINE AND REHABILITATION RESIDENCIES — Two to three year residencies at the Veterans Administration Hospital, Minneapolis, affiliated with the University of Minnesota. Stipend \$4,160 to \$12,873. Inquire Chief, Physical Medicine and Rehabilitation, Veterans Administration Hospital, Minneapolis, Minnesota 55417.

WANTED: General Surgeon to associate with six man group. Progressive Northern Minnesota Junior College Town. Modern 150-bed hospital. Excellent hunting and fishing. Near Metropolitan Area. Contact: Falls-Starekow Clinic, Thief River Falls, Minnesota.

LOCUM TENENS: Want Minnesota licensed GP to take over practice for June, July, August. Living accommodations, excellent salary. Write: MINNESOTA MEDICINE — 376, 496 Lowry Medical Arts Building, St. Paul, 55102.

A man will sometimes devote all his life to the development of one part of his body — the wishbone. — Frost

Business is business.

Says who? Says too many people.

You've probably heard it yourself many times.
It's used to justify almost *anything*.

But how many times have you ever questioned this attitude or raised your voice in protest? An idea like this takes root just because not enough people do anything to stop it.

If you have ever asked yourself "Why doesn't someone do something about it?" you're talking to the right person. You.

It won't be easy. Sometimes you'll need encouragement. The kind you'll find in your place of worship.

Here you'll discover you're not alone. That, in itself, can give you the strength to say "Says who?" once in a while when it needs to be said.

Blood Group Antibodies in Prenatal Sera

Results
of
Screening
43,000
Individuals*

HERBERT F. POLESKY, M.D.**
Minneapolis, Minnesota

SINCE LEVINE and Stetson's original observation in 1939¹ of the role of isoimmunization in the etiology of erythroblastosis fetalis, it has become almost universal practice to test for anti-Rh^o (D) antibodies in the sera of Rh negative, pregnant women. During the same period of time, the number of established blood groups has expanded from three to fifteen. There are now well over 100 documented blood group antigens, making it possible to recognize over a million individual combinations of blood group factors. Many of these antigens have been found as the result of maternal sensitization, hemolytic disease of the newborn, and transfusion reactions. In the last six years, sera from 43,000 pregnant individuals have been studied on one or more occasions for atypical blood group antibodies, at the Minneapolis War Memorial Blood Bank. It is the purpose of this paper to report the results of this screening program and to discuss the significance of the antibodies found.

Materials and Methods

Five to 10 cc. samples of clotted blood were received by mail.

Erythrocytes were typed with anti-A, anti-B, anti-A,B (O serum), anti-Rh^o(D), anti-rh'(C), anti-rh''(E), anti-hr'(c), and anti-hr''(e). The patients' sera were checked with known type A₁, B, and O erythrocytes. Each serum was screened for antibodies with a pool of red cells from three selected donors. These cells contain the majority of antigens likely to occur in the population being tested. The same donors were drawn every two weeks and their cells stored in ACD solution without preservatives. The screening procedure used was as follows:

1. Incubation of 2-4% saline suspension of selected donor cells with 0.1 cc. of patient serum at 16 to 20°C. for one hour.† Continued

*Presented in part at the Minnesota Association of Blood Banks meeting, May 4, 1966, Minneapolis, Minnesota.

**Assistant Professor, Department of Laboratory Medicine, University of Minnesota and Director of the Minneapolis War Memorial Blood Bank.

†Sample centrifuged and observed for agglutination and hemolysis.

2. Incubation of the same suspension at 37°C. for one hour.*

3. Previous incubation mixture washed three times and antihuman globulin added.*

4. Incubation of 2-4% suspension of washed, papainized, pooled cells with 0.1 cc. of patient's serum at 37°C. for 30 minutes.*

5. Incubation of 2-4% suspension of selected pooled cells with one drop of 30% albumin and one drop of patient's serum at 16-20° for 10 minutes.*

Identification of the antibody or antibodies in all sera with a positive screening test was carried out with a panel of erythrocytes of known antigenic composition. The same donors used in the screening pools form part of the panel which was supplemented by frozen cells to aid in the identification of

*Sample centrifuged and observed for agglutination and hemolysis.

TABLE 1
Antibodies To Rh Antigens

	Number Of Individuals With Antibodies		
	Rh ^o Positive	Rh ^o Negative	Total
Anti-Rh ^o (D)	—	1412	1412
Anti-rh'(C)	2	3	5

multiple and/or rare antibodies. Additional typing of the patient's cells and her husband's cells was performed as indicated.

Results

Of the women tested 35.2% typed as Rh negative. Of these individuals 13.9% had positive antibody screening tests. Of the Rh positive women 1.3% were found to have antibodies. Of the individuals with antibodies 82% showed specificity for antigens in the Rh system. In Table 1, the distribution of these is shown in the two groups of patients. Of the women with Rh antibodies 25% reacted positively with more than one Rh and/or other blood group factor. In Table 2, a similar comparison between the Rh negative and the Rh positive women is shown for antibodies to red cell antigens in other blood group systems. The high incidence of Lewis and Kell antibodies observed in this study is similar to the observations of Kissmeyer-Nielsen,² Bowman,³ and Giblett.⁴

Discussion

The results of this study corroborate the findings of Bowman³ that atypical blood group antibodies occur in 4% of appropriately studied prenatal sera. The higher incidence observed by us (Table 3) can be accounted for by the pre-selection of the specimens submitted for study, since our data was obtained from a group of women with more than double the expected distribution of Rh negatives. In Table 3 the 5.7% incidence of antibodies detected in our laboratory is compared with the findings reported from other centers using similar procedures.

TABLE 2
Antibodies to Other Blood Group Antigens

BLOOD GROUP ANTIBODIES

TABLE 3
Incidence of Positive Antibody Screening Tests

	No. of Patients	Antibodies	%
Rh Laboratory, MWMBB	43,000	2460	5.7
Donors, MWMBB	185,000	373	0.2
Recipients (E. Giblett) ⁴	21,000		1.3
Prenatal Sera (H. S. Bowman) ³	4,653	179	3.9
Random (F. Kissmeyer-Nielsen) ²	200,000	4168	2.1

Kissmeyer-Nielsen² found that 1/590 Rh positive individuals had antibodies. The sera he studied included donors, recipients, compatibility problems, and prenatal patients; thus his study is fairly representative of the population at large. Our data indicates that 1/77 Rh positive pregnant women is sensitized. When compared to the general population, both Rh positive and Rh negative pregnant women are highly likely to have been sensitized. In spite of the increased risk to all gravid women, the skewed distribution of the Rh type of the samples submitted for study (35% Rh negative) confirms our impression that once a woman is classified as Rh positive, it is unlikely that she will be screened for antibodies during pregnancy.

Two major categories of problems can be anticipated from the finding of atypical antibodies in prenatal sera: (1) compatibility testing may be difficult and the risk of a transfusion reaction increased, and (2) hemolytic disease of the newborn may be present. A large number of antibodies frequently encountered during pregnancy either do not cross the placenta or have a specificity to antigens weakly developed or absent in the neonate. This group which has not been reported to cause erythroblastosis, but which can cause transfusion reactions, includes anti-Le^a, anti-Le^b, anti-A₁, anti-I, anti-OH, anti-P₁, anti-N, anti-Yt^a, and Gy^a.⁵ The remainder of the antibodies detected, all potentially capable of causing severe transfusion reactions, have been reported to cause hemolytic disease of the newborn.

A more detailed examination of the data obtained on women with anti-Kell points out the importance of typing the patient's husband and the value of a history in clarifying

the possible problems that may be encountered. In Table 4 it can be seen that only 14 of 59 patients whose husbands were typed for Kell were married to Kell positive men. A history of transfusion was obtained from almost half of those individuals married to Kell negatives. Since the histories were incomplete, it is highly probable that all of these women had received transfusions at one time. Thus in those cases where the husband is kk, both the physician and patient can be reassured that the baby will not be affected by erythroblastosis and the transfusion service warned of a potential recipient sensitized to Kell. Similar situations can occur with other blood group antigens, and it is not unusual to find a woman sensitized by prior transfusion or pregnancy during a previous marriage.

TABLE 4

Antibodies to Kell	% Known to Have Been Transfused	
Number of Women with anti-K	91	31
Husband — Kell type Known	59	
Husband Kell Positive	14	14
Husband Kell Negative (kk)	45	44

Summary

Atypical blood group antibodies were found in the sera of 5.7% of 43,000 pregnant women. Of these 14.4% were in Rh positive individuals.

The finding of antibodies in prenatal serum is useful in predicting the possibility of erythroblastosis and crossmatch problems. Since the yield of such a screening program is high and can contribute to the safety of the patient, sera from all pregnant women regardless of Rh type should be tested.

INFLAMMATION: A cellular fight for life

A SYNTEX REPORT based on recently developed hypotheses about topical corticosteroids, including the cellular theories of inflammation by Thomas F. Dougherty, Ph.D., University of Utah.

You are looking at a fibroblast fighting for life. This cell—one of the most common found in connective tissue—has literally been poisoned by cytotoxins released from other cells that have ruptured. Soon, if the abnormal activity of this fibroblast does not cease, it, too, will rupture and die—one more casualty in the inflammatory wave of destruction precipitated by injury.

Until a short time ago no one had ever witnessed such a scene at the cellular level. Now, through advanced cinemicrographic techniques, it is possible to view and photograph the inflammatory process as produced experimentally in living animal tissue. This method permits new insight into the mechanism of inflammation and the role of corticosteroids in therapeutic management. Equally important, these techniques shed new light on factors that may make one corticosteroid more effective than another—factors that can be correlated with other chemical, biologic, and clinical parameters.

Visual evidence of how corticosteroids influence the inflammatory reaction

Working with phase-contrast cine-micrography on living animal tissue, Doctors Thomas F. Dougherty and David Berliner of the University of Utah College of Medicine have actually filmed cellular events that occur during the inflammatory reaction. This remarkable study* and additional work by these investigators, as well as by others, have established a new theoretical biologic basis for the antiinflammatory effect of the corticosteroids. (It must be noted that other theories, such as the lysosome or so-called "suicide bag" theory, have been postulated, although it is quite likely that there are more similarities than differences among the various theoretical models.)

The inflammatory wave of destruction

In this investigation an injurious injection of gelatin is used to set off an inflammatory reaction in living mouse tissue. What follows is a wave of destructive cellular activity that comprises the inflammatory response to injury. Mast cells (which contain heparin, serotonin and histamine) take up water, swell and rupture, releasing their contents, which are toxic outside the mast cell wall. These toxins, in turn, cause disintegration of other cells (such as fibroblasts) and the release of additional toxic material. Capillaries, too, take up water and leak unformed blood elements, causing edema. And polymorphonuclears, lymphocytes and perithelial cells invade the inflamed site. As a result of all these changes, the cellular environment reaches a state of turmoil.

Phase-contrast microscopy showing mast cell before injury.

Mast cell (after injury) has broken up and released cytotoxins.

How corticosteroids change the picture

Corticosteroids appear to virtually stop the abnormal cellular activity that constitutes the inflammatory reaction. This permits the body's natural resources to clear up the inflamed area and repair the damaged tissue. This interpretation is supported by the fact that when the injurious gelatin solution is injected simultaneously with a corticosteroid — Synalar (fluocinolone acetonide) — the inflammatory pattern simply does not develop.

Fibroblast in high state of activity, much distorted.

Mast cells showing effects of corticosteroid action: cells are normal in size, shape and activity.

In summarizing his study Doctor Dougherty states: "...we also feel this work may explain why one corticosteroid helps a patient more rapidly and effectively than another. If it does, it is because one corticosteroid is the fastest, most effective inhibitor of the series of inflammatory events at the tissue level."

*A New View of Corticosteroid Action in Inflammatory Dermatoses, a film based on this study, is now available from your Syntex representative.

How advances in chemical design have achieved greater steroid potency

The chemical modification of corticosteroid molecules from the advent of hydrocortisone to the development of Synalar (fluocinolone acetonide) is a prime example of how biochemists can "design" to increase therapeutic activity and minimize undesirable side actions. Below, for example, we see the important changes that were made in reference to the hydrocortisone molecule to produce fluocinolone acetonide, one of the most active of all topical corticosteroids. As a result, a 0.01% preparation of Synalar (fluocinolone acetonide) has been reported to do the work of a 1% hydrocortisone product containing 100 times more corticosteroid. And it can often do it more effectively.

Hydrocortisone

Fluocinolone Acetonide (Synalar)

- a double bond between carbons 1 and 2
- fluorine substitutions at both the 6- α , and the 9- α positions
- the addition of the acetonide at the 16- α , 17- α positions, thus providing one of the most potent topical corticosteroids available.

How bioassay tests are used to "predict" therapeutic potential

Biologic assays are another tool used by researchers to help establish the relative activity of corticosteroids. To date no single method of assaying corticosteroid activity has emerged as the ideal "yardstick" for predicting therapeutic potential. Taken together, however, these methods have proved useful. When such tests are run on various corticosteroids, a definite order of corticosteroid activity becomes evident. Compounds with the highest order of activity may be expected to merit clinical trial to establish their high therapeutic potential. When assayed by these methods, fluocinolone acetonide (Synalar) emerges as one of the most active topical corticosteroids, milligram for milligram, available for clinical application today.

THE THYMUS INVOLUTION ASSAY¹⁻⁴ is run on adrenalectomized rats. The sizes of the glands are measured, and the degree of involution caused by the steroid is determined as an indication of its potency. In the above photo, the comparative involution of thymus glands achieved with hydrocortisone and Synalar (fluocinolone acetonide) is shown. Untreated controls (A) show normal size. Group B— injected with 1, 2 and 4 mg. of hydrocortisone— show progressively smaller thymuses as does Group C— injected with fluocinolone acetonide— but with only 1/500th the dose of hydrocortisone.

THE ANTIGRANULOMA ASSAY¹⁻⁴ also utilizes adrenalectomized rats. Granulomas are induced by subcutaneous implantation of cotton pellets on either side of the thorax. The degree of granuloma inhibition achieved by a steroid reflects its potency. The above photo shows the inhibition of granuloma formation achieved with hydrocortisone and Synalar (fluocinolone acetonide). Untreated controls (A) show large, red granulomas adhering to the pellets. Group B, receiving hydrocortisone and Group C, receiving fluocinolone acetonide, show little, if any, granuloma formation. Fluocinolone acetonide produced the same effect as hydrocortisone with only 1/500th the dose. This assay, as well as the thymus involution assay, measures systemic rather than topical corticosteroid activity. Nevertheless, results by these methods correlate well with other assays and with the milligram potencies of topical steroids in current clinical use.

Worldwide clinical experience confirms the predictable therapeutic potential of Synalar

It is particularly gratifying that the promise of the advanced chemical design and high order of bioassay activity of Synalar (fluocinolone acetonide) has been confirmed by widespread therapeutic application. Indeed, the impressive clinical response rate of Synalar has been documented in no fewer than 232 papers from 22 countries.

PRESCRIBING INFORMATION

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; *for emollient effect:* Ointment 0.025%, 15 Gm. tubes; *for maintenance therapy:* Cream 0.01%, 15 and 45 Gm. tubes, 120 Gm. jars; *for intertriginous or hairy sites:* Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; *for infected inflammatory dermatoses:* Neo-Synalar® Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

CONTRAINDICATIONS: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. **PRECAUTIONS:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for pro-

longed periods of time. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. When severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. **SIDE EFFECTS:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. The neomycin in Neo-Synalar Cream rarely produces allergic reactions.

114th Annual Meeting

Duluth Will Host Our Annual Meeting

Mark your calendar . . .

The committee on scientific assembly has made a number of significant innovations in the format of our 1967 Annual Meeting May 15, 16 and 17 in Duluth.

For the first time we will meet in the exciting environment of the new \$6.1 million Duluth Civic Auditorium. The spacious new facility will house most of the meeting events, including the House of Delegates meetings, scientific sessions, scientific and technical exhibits, and the round table luncheons; also most breakfast meetings.

A home study course on erythroblastosis fetalis has been arranged by the committee to enable physicians to continue their education, to participate in the scientific session with greater depth, and to better serve their patients. Approximately 100 physicians have enrolled for the course, offered during the six weeks preceding the seminar on this subject, to be held Tuesday, May 16.

The presentation of a series of eleven five minute "How To Do It" talks to be given by Minnesota physicians will be one of the new features of the 1967 scientific assembly program. Topics scheduled for discussion at this session, set for 3:30 P.M. Monday, May 15, include: Warts Cooking?; Constipation — Can't or Won't?; The Plugged Catheter; Bloody Nose; Threatened Abortion; Painful Feet; Contact Lenses; The Buzzing Ear; The Discharging Nipple; How to Inject a Painful Shoulder; and The Varicose Ulcer.

A timely discussion entitled "The Intensive Care Unit — Can the Community Hospital Afford It?" will be featured at the 10:30 A.M. session Monday, May 15.

Medicine and Religion, a perennially popular subject among those attending annual meetings, will be featured at the 2:00 P.M. session Monday, May 15. "M.D., L.L.B., and D.D. — Whither Goest Thou?" is the title selected by the committee, and thorny philosophical and legal problems connected with transplants and other dramatic modern developments will be considered.

Other scientific sessions scheduled will be

devoted to dangerous drug problems, "Convulsive Disorders, Fertility and Sterility" and medical emergencies under the title, "Doctor Blue — Where Are You?"

Two groups of round table luncheons will be held, Monday and Tuesday noon. Monday round table luncheon subjects are: The Hearing Aid Problem, Dialysis in the Community Hospital and the Home, Cancer Chemotherapy, Ongoing Coronary Disease, Field Diagnosis in Athletic Injuries, The Annual Physical — Why? and The Neuter Sex.

Six luncheons have been scheduled for Tuesday noon. Luncheon topics are: Drug Incompatibilities, Erythroblastosis, Diagnosis of the Unconscious Patient, The Thrombosed Hemorrhoid, Multiple Pregnancy, and Medical and Surgical Treatment of Persistent Peptic Ulcers. Distinguished guest speakers will join local authorities as leaders for both days luncheons.

The House of Delegates will convene Sunday, May 14, at 2:00 P.M. and Tuesday, May 16, at 10:00 A.M. Our Annual Banquet, including the reception, presentations, entertainment, dancing and late evening entertainment, is set for Tuesday evening, May 16.

The Wednesday program will be devoted to current socio-economic problems.

As in the past, many scientific and non-scientific committees have planned breakfast meetings in conjunction with the scientific sessions. Also, a particularly outstanding selection of scientific and technical exhibitors has accepted the invitation to exhibit with us in the new Duluth Auditorium.

The committee extends a special invitation to all physicians to visit the exhibits, and urges them to express their appreciation to the technical exhibitors whose participation annually helps to make this meeting possible.

A complete listing of all the details of the scientific, social and business sessions will be included in the official program which will be mailed to all physicians. Consult the Annual Meeting program for complete details. Following is an abbreviated schedule of scientific events and speakers.

Scientific Program

Duluth Civic Auditorium

MONDAY MORNING, MAY 15, 1967

The program on Monday is acceptable for 4½ accredited hours by the American Academy of General Practice.

A.M. Visit scientific and technical exhibits

9:00 Doctor Blue — Where Are You?

Cardiopulmonary Emergencies in Infants — *Harold Katkov, Wayzata*

Complete Heart Block and Associated Ventricular Arrhythmias — *Stephen M. Ayres, New York*

Cardiac Resuscitation — *Carlos E. Harrison, Jr., Rochester*

10:30 Visit scientific and technical exhibits

10:30 THE INTENSIVE CARE UNIT — CAN THE COMMUNITY HOSPITAL AFFORD IT?

Wilbert S. Henke, St. Paul

Richard C. Gaard, Robbinsdale

Mr. Jerre Logan, St. Paul

Mr. Jerome T. Bieter, Hamilton Associates, Minneapolis

MONDAY AFTERNOON

P.M.

12:15 ROUND TABLE LUNCHEONS

1:30 Visit scientific and technical exhibits

2:00 M.D., L.L.B., AND D.D. — WHITHER GOEST THOU?

Eugene E. Scott, St. Paul — Moderator

Rev. Paul B. McCleave, Chicago

Thomas E. Starzl, Denver

Mr. Burr B. Markham, Minneapolis

3:00 Visit scientific and technical exhibits

3:30 HOW TO DO IT (Five minute talks)

1. Warts Cooking?

E. T. Ceder, Minneapolis

2. Constipation — Can't or Won't?

James C. Cain, Rochester

Program Highlights

- ... A unique seminar experiment on erythroblastosis fetalis open to all physicians attending the meeting, including those who did not register for the pre-seminar mailings.
- ... A series of eleven 5 minute "How To Do It" talks on such topics as "The Buzzing Ear," "The Bloody Nose," and "Painful Feet."
- ... An outstanding array of guest physicians — listed alphabetically:
 - Dr. Stephen M. Ayres of New York City, New York
 - Dr. John M. Bowman of Winnipeg, Manitoba
 - Dr. Edward A. Carr, Jr., of Ann Arbor, Michigan
 - Dr. R. F. Friesen of Winnipeg, Manitoba
 - Dr. Alan F. Guttmacher of New York City, New York
 - Dr. Thomas E. Starzl of Denver, Colorado
- ... Some friends from the American Medical Association
 - Dr. F. J. L. Blasingame
 - Reverend Paul B. McCleave
- ... Prominent lay speakers —
 - Mr. Jerome T. Bieter of Minneapolis
 - Mr. Jerre Logan of St. Paul
 - Mr. Harris W. Feldick of Osage, Iowa
 - Mr. Burr B. Markham of Minneapolis

Derivatively Speaking

Syphilis — from Syphilus, the name of a shepherd infected with the disease in the poem of Fracastorius (1530). Derived perhaps from Greek syn (together) plus philein (to love).

9500 miles from Danang, Americans are fighting another enemy.

Inflation is a threat to every family's paycheck . . . to the strength of our nation itself. And while other Americans are engaged in the fight for freedom half way around the world, we must be increasingly alert to the dangers of inflation here at home.

American businessmen can help maintain a stable economy and curtail inflationary pressures through the Payroll Savings Plan for United States Savings Bonds. Money invested in Savings Bonds is actually an investment in the United States. It results in more effective

management of the public debt, maintains the value of the dollar and provides a firm base for family security.

In your plant or office, you can initiate and promote this program for systematic savings. Complete information is available from your State Savings Bonds Director or by writing the Treasury Department, United States Savings Bonds Division, Washington, D.C. 20226.

in your plant . . . promote the PAYROLL SAVINGS PLAN for U.S. Savings Bonds

The U.S. Government does not pay for this advertisement. It is presented as a public service in cooperation with the Treasury Department and The Advertising Council.

Vital Records

Minnesota Vital Records

1967 Revision

A. B. ROSENFELD, M.D.*
ROBERT W. HILLER**
Minneapolis, Minnesota

REVISED FORMS for recording births, deaths, and fetal deaths developed by the Minnesota State Board of Health were introduced January 1, 1967. Major revisions of vital records occur approximately every ten years to coincide with the revised recommendations of the United States Public Health Service on the content of vital records. These recommendations to the states, known as the "standard certificates," along with the international classification of diseases, are the two most important instruments for achieving the nationwide comparability and consistency that are so essential in the interpretation of vital statistics data.

A great deal of study and planning have gone into the 1967 Minnesota revision. The topic of standard certificates appeared on the 1962 agenda of the biennial Public Health Conference on Records and Statistics, held in Washington, D. C. Since that time, research organizations, medical societies, hospitals, administrative organizations, law enforcement agencies, and many other groups have been contacted for suggestions and recommendations. State and local registrars of vital statistics, statisticians and other consultants served on study committees to develop specific recommendations to the United States Public Health Service on content and format.

Additional work was required to adapt

these standard certificates to Minnesota laws and practices. Valuable assistance and advice was obtained from a special subcommittee of the Minnesota State Medical Association's committee on obstetrics, gynecology, and maternal health, which included representatives from the Council of the State Medical Association, Academy of General Practice, Department of Obstetrics, University of Minnesota Medical School, and the Minnesota State Hospital Association. Additional assistance and advice were obtained from local registrars, county coroners, funeral directors and morticians.

The revised certificates have been approved by the Council of the State Medical Association, as well as by the Committee on Obstetrics and Gynecology and Maternal Health. They are consistent with the United States Public Health Service recommendations and will be easier to complete and certify. The new documents will also be easier to handle and process for statistical and legal purposes.

Birth Certificate

Substantial differences in format exist between the revised Minnesota certificate and the "standard certificate," but all the basic items on the standard form are included. The most notable difference between the revised Minnesota form and the standard form is that, as in the past, there is a supplemental form containing the medical data (confi-

**Chief, Section of Vital Statistics Minnesota Department of Health.

dential medical supplement), rather than a single form as recommended by the United States Public Health Service. This decision was made because of the general agreement that the medical portion of the form should be filed not with the local registrar, but directly with the state registrar.

The new form, which is much smaller than the old one, will be easier for the certifier to complete. Among other things, duplicate entries are no longer required since the revised supplement will be a carbon copy of the birth certificate itself, with the medical data appearing on the lower portion. This arrangement will facilitate the processing of the statistical data and the use of such data in the development of national statistics. Items relating to farm residence, usual occupation and kind of business or industry of father, length of pregnancy, use of silver nitrate, date of mother's first marriage, and the presence of a blood factor involved in erythroblastosis fetalis have been deleted. Many "check box" questions have been changed to "open end" questions to permit greater freedom to the certifier in his response.

Attention should be called to the addition of one item, namely, the name of the certifier, which is to be printed or typed. The certificate still requires the certifier's signature, but a printed name will help avoid the consternation and confusion that occurs at times in the registrar's office when a hieroglyphical signature defies all attempts to break the code.

All birth statistics will now be derived entirely from the medical supplement form. More than ever before, the collection of this essential data depends on the complete and timely filing of the medical supplements. The cooperation of certifiers in the completion and timely filing of the medical supplements will avoid the excessive costs of matching records and duplicating work to obtain basic birth statistics.

Death Certificate

The outstanding features of the revised death certificate include (1) addition of a separate medical certification statement for coroners and medical examiners, and (2)

substantial changes in the arrangement of items. Several items have been deleted, including items on farm residence, length of stay at location of death, and information on the date and major findings of surgical operations. Items have been added for the name of the funeral establishment and the birthplace of the parents.

The present medical certification form was designed primarily for the physician last in attendance. As a general rule, the coroner or medical examiner had to strike out much of the certification statement before signing it. The revised certificate contains two separate certification statements, one appropriate for the physician last in attendance and the other for the coroner or medical examiner.

Items dealing with the date and major findings of operations were deleted because of their marginal value for statistical purposes and because there was some indication that these items interfered with proper certification in Parts I and II. In some instances, for example, information on surgical procedures was omitted when it properly belonged in the certification to avoid erroneous classification of the cause of death.

The question as to whether an autopsy was performed has been expanded to include the question of whether autopsy findings were used in the precise determination of the cause of death. Answers to this question will provide a much improved measure of the reliability of mortality statistics. Because of the time element involved in completing the death certificate as opposed to the time element in obtaining a final autopsy report, it will often be the preliminary and not the final autopsy report that will be considered in the determination of cause of death. The decision to wait for the final autopsy report will depend on the nature of the particular case and on the judgment of the physician as to whether the final report will materially change the diagnosis.

There is a small box in the section of the new form for the medical certification which is to be checked if the diagnosis of cause of death is to be deferred. The certifier will no longer have to write in "diagnosis deferred," "diagnosis pending," or whatever. In addi-

tion to saving time for the physician, the check mark response will facilitate processing in the office of the state registrar because there will be space available on the form for filling in the final diagnosis. In the past, in such instances, the space was already filled with such comments as "diagnosis deferred."

The revised death certificate is almost identical to the United States Public Health Service recommendations, but they were adapted to fit state and local requirements as the result of surveys involving coroners and medical examiners on those aspects of the certificate of direct interest to them. Funeral directors and morticians were also contacted for comments on other aspects of the form.

Fetal Death Certificate

The fetal death certificate, as in the past, is a composite form. It includes information from both the birth and death certificate forms. The major feature of the revision is that the fetal death certificate is a two-page form, rather than a one-page form, with a detachable section. The medical supplement contains a carbon copy of the information on the first page, plus certain medical data on the lower portion, as is true for the birth certificate. The medical supplement to the certificate of fetal death is to be filed with the Section of Vital Statistics of the Minnesota Department of Health, as is the case for the medical supplement to the certificate of live birth.

Interest in fetal death statistics has greatly increased in recent years as medical science has sought to develop a greater understanding of this wastage of human lives that hopefully will lead to preventive measures to decrease the number of fetal deaths. Too, such data are extremely valuable in studies of human fertility. For such data to be meaningful, accurate and complete reporting are essential.

Need for Accurate Vital Records

The word "vital" as used in the terms "vital records" and "vital statistics" reflects a concern with life. Thus, vital records record the beginning and the termination of life. Whether vital records are truly vital,

essential, and important to society and to the individual depends on the uses to which such data are put.

For the individual, they serve as the basic proof of citizenship, age, parentage, etc. enabling the individual to prove entitlement to a great variety of rights and benefits.

There are numerous uses of vital records in the field of public health. Statistical data derived from the records form the basis for efficient planning of many public health programs and activities and assist in the allocation of resources to those areas where the problems are most serious.

Another major use of vital statistics is in the study and analysis of population. Such studies serve as the basis for making current population estimates and projections, which are of great importance throughout the economy, in planning investments in manufacturing plants, highways, public utilities, schools, housing, and many other activities.

Both for public health and for persons engaged in medical science research, a knowledge of the causes of death and factors contributing to those deaths are essential in the determination of needed research that will hopefully prolong life and prevent needless deaths. If more data are required today than in the past it is because more is understood about the relationship between the health of the individual and his socio-economic environment.

Too, modern society is concerned with the prevention of human wastage, whether it is fetal wastage or wastage at some other developmental stage. Where society at one time accepted as inevitable such losses as fetal deaths, maternal deaths, and high infant mortality rates, today it strives to lower these losses to the irreducible minimum.

The achievement of this common goal of public health and the clinical practice of medicine requires a precise knowledge of conditions as they exist. Certifications of births, deaths, and fetal deaths provide the basic data with which to measure these conditions, and the data so provided will be meaningful only to the extent that they are complete and accurate.

Range Medical Society Executive & General Meeting, May 23, Place not determined, 6:00 P.M.

JUNE

A continuation course in Clinical Electroencephalography, June 5-7, Philadelphia, Pa. Sponsored by the American EEG Society and is designed for physicians who have had little or no formal EEG training. Inquiries address to: Donald W. Klass, EEG Course Director, Mayo Clinic, Rochester, Minnesota.

Why Western Electric rewired its safety program to include training in defensive driving. And why you should too.

Last year, American industry lost over 22,000 trained employees killed in off-the-job traffic accidents. And 1½ billion dollars in lost time and production. But, hundreds of companies—big and small—are doing something about it. Like Western Electric. In the last two years, Western Electric trained 800 employees with the National Safety Council's Defensive Driving Course. And hundreds more are

signed up to take this complete course in new and tested concepts and techniques of defensive driving. You can do the same thing for the employees of your plant, office or facility. The National Safety Council will be glad to tell you how to set up the Defensive Driving Course in your company. And reduce traffic accidents among your employees *significantly*. Mail the coupon today.

Special Projects-Public Information

People keep asking us:

“Why do you call the

FILTER QUEEN

a sanitation system

instead of a vacuum cleaner?”

FOR THE BIG DIFFERENCE
SEE THE NEXT TWO PAGES

Only FILTER QUEEN

(The problem of overcoming increasing air pollution is one of the most urgent facing your institution and the entire community today. How FILTER QUEEN, through its unique, patented Filter Cone helps combat air pollution while it cleans, shows a picture of vital interest to every member of your hospital staff. We hope you will mark these pages and route them according to your needs.)

1. Every hospital has its dust and odor problems.

2. That's when a FILTER QUEEN is needed.

3. FILTER QUEEN quickly removes air-borne contaminants while it cleans.

QUEEN helps purify the air while it cleans!

*That is why we call **FILTER QUEEN**
a sanitation system instead of a vacuum cleaner!*

A FEW OF THE HUNDREDS OF HOSPITALS NOW USING FILTER QUEEN:

Fresno Community Hospital.....Fresno, California
Grady Memorial Hospital.....Atlanta, Georgia
Grant Hospital.....Columbus, Ohio
Henry County General Hospital.....Paris, Tennessee
Henry Ford Hospital.....Detroit, Michigan
Holy Cross Hospital.....Ft. Lauderdale, Florida
Los Angeles City Genl. Hospital..Los Angeles, California
Mass. Memorial Hospitals.....Boston, Massachusetts
Medical College of Virginia.....Richmond, Virginia
Northwestern Hospital.....Minneapolis, Minnesota
Overlook Hospital.....Summit, New Jersey
Port Huron Hospital.....Port Huron, Michigan
Queen's Hospital.....Honolulu, Hawaii
St. John's Memorial Hospital.....Anderson, Indiana
Worcester City Hospital.....Worcester, Massachusetts

The engineers who perfected the FILTER QUEEN machine clearly recognized that all bag-type vacuum cleaners cannot operate with maximum efficiency because they use a porous bag. So, to make suction cleaning action truly efficient, they had to find a way to overcome the leakage in dust and dirt that so often occurs whenever a porous bag is used.

The highly successful result was an entirely *different* air flow principle, known today as Cyclonic Cleaning Action. By using Cyclonic Cleaning Action, FILTER QUEEN'S designers succeeded in not only collecting the dust and dirt normally collected by vacuuming; they also succeeded in trapping almost invisible airborne contaminants that formerly escaped back to repollute the air.

The difference between FILTER QUEEN'S remarkable Cyclonic Cleaning Action and ordinary vacuuming becomes immediately apparent when the Smoke Test pictured at left is made. Smoke, other contaminants and offensive odors virtually disappear. The room not only smells clean—it *is* clean!

The key to this almost magic action is FILTER QUEEN'S patented Sanitary Filter Cone. (See illustration.) Inrushing air, laden with dirt and dust, is deflected by a patented inlet guide as it enters the FILTER QUEEN container, then is whirled away by centrifugal force. Foreign matter heavier than air is forced to the bottom and the sides.

Clean air is filtered through our exclusive Sanitary Filter Cone *above* floor level, leaving smoke as well as dirt and dust trapped in the container. That is why hundreds of hospitals and other institutions insist on the FILTER QUEEN Sanitation System over any type of vacuum cleaner.

Ask your local FILTER QUEEN Distributor to make FILTER QUEEN'S dramatic Smoke Test in your hospital. Then you will *KNOW* why we proudly call it a FILTER QUEEN Sanitation System instead of a "vacuum cleaner."

DOCUMENTARY PROOF: *We would like to send you, with our compliments, an article entitled "Air Hygiene for Hospitals" which appeared in the Journal of the American Medical Association. In this article it is explained what happened to airborne contaminants when a FILTER QUEEN was used in a series of rigidly controlled tests conducted at the Harvard Medical School. Write to Health-Mor, Inc., 203 North Wabash Ave., Chicago, Illinois 60601*

The FILTER QUEEN sanitary filter cone is a scientifically-designed dust separator, composed of a special long-fibred mat of pure cellulose, chemically treated to give it the necessary strength and air-filtering characteristics.

FILTER QUEEN is a product of HEALTH-MOR, INC.,
203 North Wabash Ave., Chicago, Ill. 60601.
In Canada: Filter Queen Corp. Ltd.,
252 Victoria St., Toronto, Ont.
In Mexico: Industrias Filter Queen, S. A.,
Jardin No. 330, Col del Gas, Mexico 15, D. F.

You'll find FILTER QUEEN Sanitation Systems listed in your Yellow Pages under "Vacuum Cleaners". (That's because FILTER QUEEN is fast replacing ordinary vacuum cleaners.)

FILTER QUEEN

The cleaning method that does so much more it has to be called a Sanitation System.

special formula for a special problem

*specifically formulated
for symptomatic
relief of sinus headache*

Sinus headache is not a single entity, but a chain reaction of pain. It is facial pain—deep, dull, aching and nonpulsating. It is referred pain—originating in the nose and sinuses but felt at another site. It may become generalized pain and tension in head and neck. It is one or all of these.

The Sinutab formula is designed for symptomatic relief of sinus headache.

It provides two analgesics to relieve pain and discomfort... an effective oral decongestant to reduce mucosal congestion... and an antihistamine to help control allergic manifestations.

Side Effects: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

WARNER-CHILCOTT
Morris Plains, N.J.

SINUTAB[®]

for sinus headache

Each tablet contains
150 mg. acetaminophen,
150 mg. phenacetin,
25 mg. phenylpropanolamine HCl,
and 22 mg. phenyltoloxamine
citrate.

Minnesota Medicine at a Glance

Amebic Abscess of the Liver — Farley and Linner

Page 477

An amebic abscess of the liver is a relatively uncommon disease, but in individuals who suffer from amebic dysentery due to *Entamoeba histolytica* the incidence of abscess in the liver is significant. If an individual has been in a foreign country and arrives home with an illness, this diagnosis should be considered.

Radioactive scan studies of the liver can be a valuable asset in aiding in the diagnosis of liver abscess.

A New Intra-Articular Steroid with Prolonged Anti-Inflammatory Action — Bilka

Page 483

Adrenocorticosteroids have long been known to ameliorate local arthritic manifestations by intra-articular injection. However, the duration of the relief is short, usually less than one month. Triamcinalone hexacetonide is poorly soluble in water, and when injected into joints produces the steroid effect with relief of symptoms averaging three months in duration. The material was used intra-articularly in 125 patients; 92.3 per cent received excellent relief of symptoms.

Duodenal Atresia and Maternal Hydramnios — Barr and Neel

Page 491

Although generally considered to be a surgical emergency requiring the care of a pediatric surgeon, congenital duodenal atresia is shown in this article to be treatable in the community hospital when adequately trained personnel are available. The diagnostic clues of maternal hydramnios, abdominal distention, and absence of or abnormal meconium are emphasized, as well as the classical "double-bubble" radiographic sign. The frequent association of duodenal atresia with Down's syndrome, cystic fibrosis of the pancreas, and congenital abnormalities is emphasized.

Gamma Camera — Loken et al.

Page 497

Many methods for quantitating cerebral blood flow have been attempted previously. This study presents a fresh approach to the problem utilizing a "gamma" scintillation camera with improved electronic circuitry and tubes and a freely diffusible inert indicator which can be administered without significant radiation hazard to the patient. Serial pictures permit estimations of regional cerebral blood flow during uptake and clearance phases of the tracer through the brain. An excellent discussion of the principles and techniques used appears in this report as well as suggestions for further refinements in the procedure. Ultimately it is hoped that this method will be useful in diagnosing and quantitatively evaluating localized abnormalities of cerebral blood flow in stroke and potential stroke patients.

Gastric Ulcers — Benign or Malignant — Bartness

Page 505

Accurate radiological diagnosis of benign and malignant gastric ulcers can be of enormous help in eliminating unnecessary surgery in the former and in avoiding delay in surgery in the latter. Dr. Bartness reports 98 per cent accuracy in this paper and he offers suggestions for identifying the difference.

A Potent Diuretic — Grand Rounds

Page 573

Ethacrynic acid, a relatively new diuretic drug, is readily absorbed in the gastrointestinal tract and has a maximum effect in two hours, with a duration of action extending over eight hours. Though it has a few undesirable effects, it has proven to be effective when all other diuretics have failed. Because of the associated loss of potassium chloride, it is recommended that potassium chloride should be given during the treatment with ethacrynic acid.

Blood Group Antibodies in Prenatal Sera — Polesky

Page 601

Almost 6% of pregnant women have typical blood group antibodies. A knowledge of these antibodies may be useful in preventing hemolytic disease of the newborn and may be essential in preventing transfusion reactions. Routine screening of serum from all pregnant women, Rh+ included, is indicated by the results of this report.

whatever their color,
shape, or size...

Benadryl[®]

(diphenhydramine hydrochloride)

PARKE-DAVIS

for control of
allergic symptoms

Whether the allergen is greenish or garish, unseen or unknown, your patient can get symptomatic relief with BENADRYL—the potent antihistamine with antispasmodic action. **INDICATIONS:** Antihistaminic, antispasmodic, antitussive, and antiemetic therapy. **PRECAUTIONS:** Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with diphenhydramine hydrochloride should be prescribed with caution because of possible additive effect. Diphenhydramine

The pink capsule with the white band is a trademark of Parke, Davis & Company.

has an atropine-like action which should be considered when prescribing diphenhydramine hydrochloride. **ADVERSE REACTIONS:** Side effects are generally mild and may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, blurring of vision, vertigo, headache, muscular aching, thickening of bronchial secretions, restlessness, and insomnia have been reported. Allergic reactions may occur.

BENADRYL is available in Kapseals[®] of 50 mg. and Capsules of 25 mg.

Diagnosis:

cystitis?
pyelonephritis?
pyelitis?
urethritis?
prostatitis?
in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.d.
(initial adult dose)

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function. Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not be arbitrarily doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately 25 mg. per pound of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not be arbitrarily doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of 500 mg. for adults, conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. 250 mg. for children, available in bottles of 56 and 1000.

References: (1) Based on 23 clinical papers, 1512 cases. Bibliography on request. (2) Bush, I. M., Orkin, L. A., and Winter, J. W., in Sylvester, J. C.: Antimicrobial Agents and Chemotherapy—1964, Ann Arbor, American Society for Microbiology, 1965, p. 722.

NegGram

Brand of
nalidixic acid
a specific anti-gram-negative

eradicates most urinary tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.

- "Excellent" or "good" response reported in more than 2 out of 3 patients with either chronic or acute gram-negative infections.¹

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: E. coli, Klebsiella, Aerobacter, Proteus, Paracolon or Pseudomonas?... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Picture of bursitis

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

President's Letter

ONCE AGAIN, in an abbreviated form, let me call your attention to the fact that we will meet in Duluth in just a few days for the 114th Annual Meeting. This will be a truly historic meeting, especially from the scientific standpoint. An entirely new and exciting type of session awaits your participation. We urge you to attend and give your support. *It's your meeting.* Make it a better one by being there!!!

There are still too many of our own association members, even though their actual numbers are not great, who do not pay their A.M.A. dues. It is true that our combined dues increased this year by \$50.00, and for some of you perhaps more than this. So what?? Ask the average metropolitan worker what his union dues are. Ask him also what his average hourly wage is. Figure out the percentage and see where you stand, even when you pay your whole freight bill as most of us are doing.

Then ask yourself why you are not paying some portion of your dues. We do not have the "check-off" system. We have the "honor" system instead. Not only is it a privilege to belong to such a great organization as the American Medical Association; it is an obligation as well. Maybe you have a personal difference of opinion with some of the established policies. All rules have to be arrived at by compromise, and someone has to give at times, even on a sorely contested point.

True, we've had some crucial dissensions

in the past few years. These have been times of crisis for the entire profession; they still are. Is this the time to weaken our structure? I refer you to Dr. Buckley's President's Letter of April, 1966. It is excellent and hits this subject from a somewhat different angle. Your dues *and* participation in the affairs of medicine are sorely needed at this juncture. Now is no time for pettiness, especially in major affairs which affect all of us.

The social planners would like nothing better, believe me, than to have us create schisms amongst ourselves by failing to support our medical organizations: county, state and national. I'm sure many of them are gloating over the arguments and vituperation Medicare has caused between doctors. We must consider the overall effect our words and actions will have on Medicare as a whole and try to bury some of these dissensions in the spirit of genuine compromise. If I sound "preachy," I mean to. I would feel that I had failed as your President, if I did not speak out as I think I ought to.

Once again it is a real pleasure to call to your attention those grand people, the newest additions to our Fifty Year Club, whom we have featured in this issue.

Neurogenic Tumors in the Head and Neck

LUIS G. KRAUSE, M.D.*
SIMON TOMASISI, M.D.**
Mexico City, Mexico

THE OCCURRENCE of tumors from nerve origin in the head and neck area is rather infrequent,⁷ excluding intracranial and skin tumors. From a total 15,968 new patients studied at the Oncology Institute, 783 belonged to the head and neck service. Within this group, fifteen cases revealed neurogenic tumors, and they are the subject of this communication.†

Clinical Aspects

Incidence and Age

Neurogenic tumors in the head and neck area comprised 1.9% of the cases. Eight occurred in males and seven in females, with an age average of 33.5 years. The oldest patient was 73 years old and the youngest 11 years old.

Symptoms

There are no symptoms that are uniformly present.² In seven cases the initial symptom was a palpable or visible mass; in two cases it was pain and in three cases a combination of both. Nerve paralysis was found in one case, and paresthesia was encountered in two cases along with a palpable mass. Three tumors produced dysphagia and one produced spells of coughing on palpation — all as a result of their peculiar location.

Nerve Trunks

The vast majority of the lesions occurred in a *major nerve trunk*, but in a few cases no connection with a major trunk could be demonstrated.

*Associate Professor of Surgery, National University of Mexico, School of Medicine. Chief, Department of Head and Neck. Hospital of Oncology, National Medical Center of the Mexican Institute of Social Security.

**Associate Professor of Histology, National University of Mexico, School of Medicine. Pathologist, Hospital on Oncology, National Medical Center of the Mexican Institute of Social Security.

†The Medical records of the Hospital of Oncology of the National Medical Center of the Mexican Institute of Social Security were examined from the time the hospital opened in May 1961 through December 1965.

Location

Tongue

The most common location in the mouth is the tongue.³ Neurilemmomas* of the oral portion of the tongue have been described, but their location in the base of the tongue

*See Test Your Word Score Page 687.

Fig. 1 — Eleven-year-old boy with a neurolemmosarcoma of four months evolution in the right parotid area. (Case 2).

Fig. 2 — Thirty-seven-year-old male with a neurilemmoma of three years evolution located in the base of the tongue. Intra-oral view showing elevation of the right side of the base of the tongue. (Case 8).

is a rarity. In this situation early dysphagia is noted plus a visible and palpable mass in the subdigastric area and on intra-oral examination. In this series the only intra-oral case was found in the superior vestibular sulcus. Oral neurilemmomas behave in the same way as neurilemmomas found in other areas.^{4,5}

Parapharyngeal

The parapharyngeal location of the neurogenic tumors is usually associated with the last four cranial nerves, the cervical sympathetic or the parasympathetic nerves; consequently, hoarseness or Horner's syndrome can be found.^{6,7,8,9,10} In our series, direct relation with the vagus nerve could be demonstrated in one case. Since tumors in this location grow in an unyielding space, signs and symptoms of pressure on the neighboring structures can be observed. The larger tumors can displace the main vessels of the neck and encroach upon the alimentary canal.

Lateral Neck and Supraclavicular Region

Localization in the lateral part of the neck and in the supraclavicular area was the most prevalent position in our experience, with six cases in such a location. They were usually asymptomatic except for the visible deformity. When symptoms appear they are due in most instances to intraspinal prolongation of the tumor. These dumbbell type tumors have their origin in one of the spinal nerves, and careful radiological examination often discloses pressure destruction of the cervical vertebrae. One of the cases in this series was of this variety, arising from the second cervical root and encroaching upon the upper cervical spinal cord.

One tumor presented as a swelling in the right cheek. The clinical impression was that of carcinoma of the maxillary antrum, although the radiological study did not show bone destruction. Another case presented as a round mass at the middle third of the sternocleidomastoid muscle.

Histology

Neurilemmoma

There are two different types of nerve tu-

TABLE
Case Reports

Case No.	Age Yrs.	Sex	Date of Study	Clinical Findings	Size of Tumor	Diagnosis Pre-op	Diagnosis Post-op	Aspiration Biopsy	Treatment	Nerve of Origin	Neurological Sequelae	Results

mors. The first type arises from Schwann's cell and is called neurilemmoma. It is now generally accepted that Schwann's sheath cells give rise to the lesion; but Penfield and Tarlov's^{15,16} opinion that they originate from the fibroblast of the epineurium cannot be discarded and perhaps both theories are partially correct.

The term neurilemmoma has the advantage that it indicates the origin of the tumor and has brought uniformity in terminology, making different terms formerly used obsolete.^{11,17}

The microscopic aspect has two main patterns: the so-called Antoni A and Antoni B types.¹⁸ Type A is easily recognized because of its delicate arrangement of connective tissue and reticular fibers in serpentine and branching formations. The interposed nuclei are seen aligned in rows forming a palisade, and the whole formation assumes an organoid* appearance called the Verocay body. This peculiarity makes it quite easy to confuse these tumors with those of smooth muscle origin.¹⁹ For this reason it is felt that the histologic aspect alone is sometimes insufficient, and before a tumor is classified as neurogenic an effort should be made to show macroscopic evidence of connection with a nerve trunk. The Antoni B type is characterized by loosely arranged cells set haphazardly in a mesh of delicate reticulum fi-

Fig. 4 — Thirty-nine-year-old female patient with a neurolemmosarcoma of the left vagus nerve. Coughing spells could be induced when the tumor was palpated. She had a full-blown Von Recklinghausen disease. (Case 15).

Fig. 3 — Twenty-one-year-old female with a neurolemmosarcoma of the second cervical root, left side. Notice the tumor mass located between the first two cervical vertebrae showing flecks of calcium. (Case 12).

Fig. 5 — Same case as in Figure 4 following surgery.

bers, alternating with cystic spaces. In the capsule of the tumor, nerve fibers belonging to the nerve can be identified.

The malignant variety, the neurolemmosarcoma, is a firm, poorly encapsulated tumor with tendency to invade the surrounding tissues. It has a white greyish appearance, and areas of necrosis and hemorrhage are commonly found. Microscopically there is proliferation of fusiform cells arranged in bands separated by reticular fibers that form a mesh. When some nuclei are found with a tendency to form a palisade, the nerve origin can be assumed more safely.

The largest neurilemmoma measured 8 cm. In one case a typical neurolemmoma alternating with areas of a neurolemmosarcoma was distinctly identified. The largest neurolemmosarcoma measured 14 cm.

Neurofibroma

The neurofibromas are benign, well circumscribed tumors when they arise from nerve ends, and well encapsulated when they arise from nerve trunks. Very often they are multiple, as opposed to the neurilemmomas. The largest neurofibroma measured 13 centimeters in length.

Microscopically, proliferation of nerve fibers along with Schwann's cells can be demonstrated, and the fibrillar loose component is predominant, intermingled with some nerve and reticular fibers. (The neurofibrosarcomas are not discussed here because none were present in these series.)

Coexisting Tumors

In two instances the neck tumor coexisted with a full-blown Von Recklinghausen disease. In another case, the neurilemmoma coexisted with a low-grade liposarcoma of the gluteal region.

There were 10 benign tumors (six neurilemmomas and four neurofibromas) and five malignant tumors (all five neurolemmosarcomas) in the present series.

Diagnosis

When the lesion arises in the lateral portion of the neck, several other pathological conditions must be considered, such as a carotid body tumor, metastatic adenopathy,

Fig. 6 — Neurilemmoma. Antoni A on the top and Antoni B on the bottom. (Case 8).

Fig. 7 — Well differentiated neurolemmosarcoma infiltrating bone tissue. Top: low magnification. Bottom: high magnification. (Case 12).

lymphoma, etc.

Of the 15 cases reported here, a correct preoperative diagnosis was made in five cases. The diagnoses made erroneously are indicated in the chart. In three cases the neurogenic nature of the growth was suspected and they were thought to be malignant while they proved to be benign; whereas in a fourth case the lesion was assumed to be benign and was found to be malignant.

In the absence of known tumor pathology elsewhere, the possibility of facing a neurogenic tumor in the head and neck area should be considered whenever a solitary, well limited, partially mobile rubbery mass is encountered in a major nerve trunk. However, a definite diagnosis can not be made short of biopsy or surgical removal of the lesion. We performed aspiration biopsies in five cases; one was reported as doubtful, two as benign neurogenic tumors (both correct), and one as a sarcoma, without stating the possible tissue of origin. In the fifth case 18 cc. of dark-stained fluid were obtained but no cytologic diagnosis could be established. We agree with Harrison and Anderson²¹ that there is a high degree of inaccuracy when the diagnosis is based on a frozen section alone.

Treatment

If the lesion is small and easily accessible a biopsy is not necessary and resection of the tumor can be both diagnostic and therapeutic. We believe resection is indicated in slow-growing benign lesions because of the pressure symptoms that are likely to occur and because of the cosmetic deformity.

All cases in this series were treated surgically. Only two cases had received previous therapy. One case had received radiotherapy without previous tissue diagnosis and the other had had local excision of the tumor.

We agree with Slaughter¹ and others that the cervical external approach is the best. Only small, easily accessible and submucosally located lesions should be removed by the intra-oral route. The external approach offers good exposure, easy control of bleeding, preservation of the immediate surroundings (especially of the nerve that has given

birth to the tumor); and the fact that the mucosa remains untouched affords a non-contaminated operative field minimizing the chances of infection.

When dealing with a benign lesion, the experience to date indicates that local excision of the tumor is curative therapy. Even in the occasional case when part of the capsule of the tumor has been left behind in order to preserve the continuity of the nerve fibers running along it, no recurrences have been encountered. This is a far better method than to leave the patient with neurological sequelae for a benign lesion. In order to achieve this, the dissection must be performed with the utmost care, often within the capsule and dissecting parallel to the direction of the nerve fibers. When dealing with a malignant case the dissection must always be done extracapsularly, and at times the surrounding tissue attached to the growth has to be excised en block.

A review of the literature indicates that radiation therapy and chemotherapy are of no value in the treatment of these tumors.

Results

In the present series two out of five malignant cases were considered non-resectable and the patients died 10 and 36 months after the diagnosis was made. One of them had a dumbbell tumor encroaching upon the cervical spinal chord. Two patients are alive and free of disease: one after three years and one after just two months. The fifth case, a diabetic patient, developed acute pneumonia two months after surgery and died of this complication. All benign cases are still alive and free of disease.

Prognosis

In benign cases the outlook is excellent and the chances of recurrence practically non-existent. If no neurological sequelae are left, recovery is complete. In malignant cases the prognosis is guarded except where the lesion is predominantly a benign tumor with only small nests of low-grade sarcoma. The frankly malignant cases invade surrounding structures early in the course of the disease

and curative surgery can seldom be accomplished.

Conclusions

Aspiration biopsy may be helpful in the diagnosis of neurogenic tumors of the head and neck.

Surgical excision through the external cervical approach is the treatment of choice,

with care taken to preserve the neural structures.

Radiological studies are of no value as diagnostic tools, except for confirmation of the presence of a soft tissue mass or vertebral destruction.

Radiotherapy and chemotherapy have no place in the treatment of this lesion.

The Frontier Doctor II*

Doctors on the frontier fought Indians, built cabins and roads, and also wrote reports on meteorology and anthropology. They searched the woods and prairies for herbal substitutes for hard-to-get eastern drugs. Between their grueling rides to succor the sick and injured, some of them built laboratories and tried to advance the sum of medical knowledge. They argued for sewage disposal, tried to regulate bawdyhouses, and denounced heavy drinking and the sale of tainted meat. In California mining camps they attempted to stamp out opium smoking among the Chinese. Ranchers and sodbusters cursed doctors who insisted that they abandon wells tainted with typhoid. They resented the doctors' demand that families sick with communicable disease be quarantined. It was not neighborly to let those nice folks down the road suffer with diphtheria without stopping by to bring them a cake and a little sympathy. The doctor had no heart.

— Richard Dunlop: M.D. Doctors of the American Frontier

The Mithridaticum

Mithridates lived in constant fear of being poisoned, to overcome which, he tested a large number of poisons on criminals and prisoners of war, and took small, increasing doses of poisons and antidotes during the greater part of his life. Today we use the term mithridatism in medicine to denote the insusceptibility to the effects of poison produced by taking a series of gradually increasing doses. . . . When Pompey defeated Mithridates (66 B.C.) he found the prescription for this very complex general antidote, together with other medical manuscripts with the king's body. This famous prescription became known as the Mithridaticum.

The Mithridaticum was improved especially by Nero's personal physicians and its use extended to a great number of ailments. There were two principal formulas named for Nero's physicians respectively, one having fifty-five ingredients, and the other seventy-two. In Nero's time these complex prescriptions became known as Theriacs, the word being derived from the snake called tyrus, the flesh of which was added to the ingredients by Andromachus, Nero's doctor. Directions for making theriacs are to be found in all dispensaries down to those of the 19th century.*

What's Your Diagnosis?

A 29-year-old right-handed man was in excellent health until four weeks prior to hospitalization when stiff neck and occipital headache developed. These symptoms would be present for two to three hours, would subside, and would recur approximately three times a week. Two weeks later unsteadiness in walking developed with a tendency to fall to the right. One week prior to his hospitalization nausea and vomiting developed.

On his admission to the hospital, his temperature was 100.2° F., blood pressure 128/80 mm. of mercury, and pulse 72 and regular. No abnormality of the cranial nerves was found except for bilateral early papilledema. There was no nystagmus. He did not have a stiff neck. He had generalized hyperreflexia but the toes turned down on plantar stimulation. Results of the finger-nose and heel-knee tests showed evidence of moderately severe cerebellar ataxia on the right and a minimal amount of cerebellar ataxia on the left. There was some hypotonia on the right.

The hemoglobin measured 14.7 Gm.; leukocytes numbered 6500 with a normal differential cell count. Roentgenograms of the cervical portion of the spinal column and of the head did not show evidence of any abnormality. An electroencephalogram showed delta waves, grade 1 biparietal occipital, maximal on the left, and generalized dysrhythmia, grade 2. Special contrast studies were then performed by a neurosurgeon. What's Your Diagnosis? Turn to page 648.

One sees the past better than it was; one finds the present worse than it is; one hopes for a future happier than it will be. — Mme. d'Épinay

Sedimentation Rate in the Normal Menstrual Cycle or with Oral Contraceptives

THE ERYTHROCYTE sedimentation rate is a commonly used laboratory test. The purpose of this study was to determine if any alterations in the erythrocyte sedimentation rate occurred in women at different times in the normal menstrual cycle or in women who are taking either a combination or a sequential type of oral contraceptive.

Methods and Materials

A fasting antecubital venous oxalated blood sample was drawn from each volunteer at the University of Minnesota Hospitals between 0800 and 0900. The erythrocyte sedimentation rate was determined at 20, 40 and 60 minutes by the method of Westergren.¹¹ In most instances more than one determination was performed on a given woman at different times during the study and she therefore served as her own control. The statistical calculations then involved correlated pairs, and the data were analyzed by calculation of the means, standard errors, student's "t" values, and probable (p) values. If the p value was greater than 0.05 the result was considered to be not significant.

Results

Menstrual Cycle

Eighteen normal women were studied on the fifth and again on the 25th day of a menstrual cycle. Each cycle was a normal ovulatory type as determined by basal body temperature graph. Table 1 shows that the erythrocyte sedimentation rate values are not different at the two test times in these women.

Minneapolis, Minnesota

*From the Department of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minnesota 55455.

This study was supported in part by funds from the National Institute of Child Health and Human Development Grant HD01463, The Population Council of the Rockefeller Institute Grant M 65.111.

Combination Oral Contraceptives

Two studies were done with a combination type oral contraceptive which contained 5.0 mg. norethynodrel and 0.075 mg. mestranol.* The first study involved 26 normal women who had an erythrocyte sedimentation rate determination done prior to taking these drugs and then again on pill day 18 to 20 of the sixth cycle of these drugs taken in the usual manner. The results in Table 2 show a significant rise in the erythrocyte sedimentation rate values after taking the drugs.

The next study involved 44 normal women who had erythrocyte sedimentation rate determinations done during the 12th treatment cycle on pill day 18-20. These women received the same drugs. The erythrocyte sedimentation rate results in Table 3 are elevated to the same degree as those listed in Table 2.

Sequential Oral Contraceptives

Twenty-eight normal subjects were tested in the control state and then again on pill day 18-20 of the sixth cycle of the usual sequence of 2 milligrams chlormadinone acetate and 80 micrograms mestranol.** The results of these tests in Table 4 again show that the drugs caused an elevation in the erythrocyte sedimentation rate.

Discussion

Robin Fåhræus in 1918, looking for a new pregnancy test, was the first to observe that the erythrocyte sedimentation rate was elevated in normal pregnancy.³ He noted that the mean erythrocyte sedimentation rate for men was 3.3 mm/hr., for nonpregnant women 7.4 mm/hr., and for pregnant women 44.9 mm/hr. Many studies have since confirmed these observations.^{5,8,10} The erythrocyte sedimentation rate, therefore, must be cautiously used during pregnancy as a laboratory aid to diagnosis and treatment.²

The normal erythrocyte cell membrane contains a glycolipid which decelerates the erythrocyte sedimentation rate and also is

a receptor site for the adsorption of certain plasma proteins called agglomerins which accelerate the erythrocyte sedimentation rate. In general, fibrinogen and the alpha globulins accelerate and albumin decelerates it.^{3,12} The erythrocyte sedimentation rate is also influenced by the erythrocyte concentration. Because the albumin level is de-

creased and the fibrinogen and alpha globulin levels are increased it is easy to understand why the erythrocyte sedimentation rate is accelerated in pregnancy.⁷

The effect of other female conditions on erythrocyte sedimentation rate is less well known. Wintrobe¹² observed that the erythrocyte sedimentation rate does not change during the menstrual cycle. Hamilton⁵ produced an elevation of the erythrocyte sedimentation rate by injections of estrogen and progesterone but not with chorionic gonadotropin. Because there are currently millions of women taking oral contraceptives and because there have been no previous reports on the erythrocyte sedimentation rate in these women, the present study was undertaken. In this study it was shown that both the combination and sequential type of oral contraceptives elevated the erythrocyte sedi-

mentation rate. This elevation is probably the result of a plasma protein alteration similar to that which occurs in pregnancy.^{1,6} Regardless of the cause, the clinician who uses the erythrocyte sedimentation rate as a diagnostic aid must be aware of the elevating effect of oral contraceptive drugs if the result is to be interpreted properly.

Conclusion

The erythrocyte sedimentation rate was measured in normal women before and during the taking of certain oral contraceptive drugs. These measurements showed no change in the erythrocyte sedimentation rate during the normal menstrual cycle. There was an elevation in the erythrocyte sedimentation rate among those women who took either the combined or the sequential type of the oral contraceptive.

Acute Abdominal Syndrome

Goldstone and Le Marquand* described a syndrome observed in 13 European servicemen on duty in West Africa that simulated acute abdominal disease. The condition was characterized by fever, right upper abdominal pain, and muscular rigidity. Symptoms appeared gradually, reaching a peak within a few hours. The pain sometimes spread to the entire right side of the abdomen and loin. Considerable rigidity was present with relatively less tenderness in the painful areas. Usually there was diminished movement of the right side of the chest and diaphragm, occasionally accompanied by shoulder pain. The prognosis was good with a rapid, spontaneous improvement in most cases. Goldstone and Le Marquand concluded that these patients most likely had an abortive form of perinephric staphylococcal infection. They also suggested that cases which simulate a perforated peptic ulcer with negative findings at operation may be similar to those described here.

Green Medicinals

Herbs for the Kidneys and Bladder

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them. Remedial agents for the kidneys and bladder include basil, cardoon, foxglove, gorse, juniper, leek, pellitory of the wall,* rest-harrow, and watercress.

For anyone with gorse buds on hand the following recipe might be used to advantage:

To Pickle Gorse Buds

Make a strong pickle of white vinegar and salt, able to bear an egg. Stir very well till the salt be dissolved, clearing off the dregs and scum. The next day pour it from the bottom, and having rubbed the buds dry, put them up in a pickle glass, which should be frequently shaken until they sink under it, and kept well stopt and covered. — Acetaria, 1622

Buckle Up

Following too Closely

The largest single factor contributing to freeway accidents is following too closely. Remember that stopping distances are longer at higher speeds. Following too closely, particularly behind trucks, reduces visibility of signs and traffic ahead. The number of feet for minimum following distance should be twice the miles per hour of speed.

Have a Good Trip

And finally, have a good trip. It takes one-third to one-half less time to travel on freeways. Travel is more economical. Fuel, wear and tear on your car are saved. Freeways are the safest means of motor travel yet devised. The rest is up to YOU.

Accept YOUR responsibility.

Answer to What's Your Diagnosis

(From page 644)

Ventriculography showed dilation of the entire ventricular system down to the middle of the aqueduct, which was displaced upward and forward by a mass in the posterior fossa.

Suboccipital craniectomy was performed. When the dura was opened the cerebellar tonsils were found to be herniated through the foramen magnum, on the right more so than on the left. A large cystic hemangio-endothelioma was found in the right cerebellar lobe.

The Disturbed Patient?

RICHARD R. BABB, M.D.*
RICHARD M. STEINHILBER, M.D.**
Rochester, Minnesota

THE BASIC REQUIREMENT for a good doctor-patient relationship is mutual respect on the part of two mature people, each of whom acts with understanding and sympathy for the human efforts, tribulations, and limitations of the other."¹

Central to the success of any therapeutic effort is a satisfying interpersonal relationship between the doctor and the patient.² Although aware of the rapid advances in technical and scientific knowledge that have allowed the medical professions to prevent, treat, and cure an increasing number of diseases, the suffering patient continues to look to the physician (and other medical personnel) for compassion and understanding as well. When such hopes are not fulfilled, the ensuing disappointment leads to tension in the doctor-patient interaction. If communication breaks down, the patient may seem "disturbed" in the eyes of the medical staff and be referred for psychiatric evaluation.

Illustrative Cases

Case One

A 39-year-old man was hospitalized because of recurrent chest pain. After a gastrojejunostomy elsewhere for peptic ulcer, he had been plagued by pyrosis for the preceding five years. Numerous hospitalizations had been required for relief of pain, and he was currently unable to work. After appropriate studies the diagnosis of diaphragmatic hernia and reflux esophagitis was made.

A psychiatric consultation was requested because of the patient's "psychopathic personality." The request had been precipitated by his recent "unmanageable" behavior.

Before the patient was interviewed, his behavior was discussed with the medical residents and nursing staff. The head nurse stated that he wandered about the halls at night and never seemed to be in bed. Early one morning, after considerable search on the medical floor, he had been located in the basement coffee room. He stated that he had attended early Mass and had stopped there on the way back to his floor. The head nurse, however, was disinclined to believe this "excuse." Furthermore, she was annoyed at his constant complaining of pain and

*Resident in Medicine, Mayo Graduate School of Medicine (University of Minnesota).

**Section of Psychiatry, Mayo Clinic.

wondered why he did not work more. Another nurse and a nurse's aid engaged in caring for the patient were interviewed. Both agreed that he was a "problem" for the reasons stated above, but they knew very little of his medical history, the nature of his pain, or why he seldom seemed to be in his room. One had heard the doctor mention "psychopath," and she knew this was not good. All agreed, however, that he was cooperative and pleasant and that he did not annoy other patients.

The medical resident regarded the patient's pain as mainly organic. When asked about the word "psychopath," he stated that this impression had been garnered from the patient's poor work record over the past five years. This resident was not particularly fond of the patient and was upset over the "management difficulties" he presented. When asked to be more specific, he replied that this was an impression he had received from the nurses and pointed to the recent incident of "lying" about chapel attendance.

The patient was next interviewed. He was upset by the consultation; it seemed to confirm his suspicion that no one believed that he had pain. Being from a poor Illinois farm family, he had worked long, hard hours throughout his teens and had then joined the armed forces, hoping to make the service a career. However, he had been discharged because of a peptic ulcer. Since then he had been unable to hold a steady job because of the chest pain. He had never acted asocially and had no criminal record. Currently, he was depressed over the inability of the medical profession to cure his pain. As for walking in the halls: "Who wouldn't want to get out of these cramped rooms?" He denied any unpleasanties with the nursing staff but was visibly upset by the chapel incident. When asked to produce proof that he had actually attended chapel, he found a nurse who corroborated his story that he had told another nurse where he was going. Finally, a patient was located who had attended chapel with him.

Our opinion was that this patient was not a "psychopath" but rather an introverted, passive, and rather inadequate personality type who was perhaps using the chest pain unconsciously as a means of escaping economic and social competition.

This case illustrates how a breakdown in communication can lead to increasing distrust and hostility between physicians and nurses and their patient. The epithet "psychopath," and indeed the psychiatric referral, would seem to have been a form of punishment for this patient. His poor work record made him suspect in the eyes of a doctor, and his lack of physical passivity cast him as a "management problem" for the nurses.

Case Two

A 37-year-old housewife was hospitalized because of recurrent chest pain of two months' duration. Physical examination and numerous laboratory tests

failed to reveal any structural causes for the pain. During the first two weeks the pain became more intense and required narcotics for relief. The patient had become increasingly uncooperative about further diagnostic procedures, and a psychiatric consultation was requested because of her "hysteria."

The initial interview revealed an angry and depressed patient. She had been hospitalized several times in the past because of neurotic depression, and had been hopeful that physicians at this clinic would not think this pain was "in my head." She stated that the intense pain was abrupt in onset, often causing her to cry out for relief. There had been several arguments with the nurses about her disturbing the other patients, although she felt that others in the four-bed room "carried on more with pain than me." This had culminated by her being moved to a private room. She was incensed over this because she could not afford it, because she thought she was being "picked on," and because no one had explained to her why it was being done. She stated that a physician had told her that when she could control her reaction to pain she would be moved back. She felt much worse than she had on admission and wanted to leave the hospital.

The medical resident stated that the patient was probably a malingerer and, at least, a "hysterical patient." To him she was difficult to manage, overcritical, and always complaining. He regarded her pain as "functional" and defended the transfer to a private room as necessary for the other patients' welfare.

The three nurses intimately involved in this patient's care were next interviewed. Two regarded her pain as imaginary ("all in her head") and were upset that she complained so much about it. They disliked her disheveled appearance; one stated, "She's too fat anyway." When asked about the move to a private room, all agreed that she had not been forewarned. They hoped we would take over her care. As one put it, "I don't even like to go into her room."

Subsequently, the patient agreed to being transferred to the Open Psychiatry Unit. The first few treatment hours were spent allowing her to review the frustrating experiences noted above. Psychosomatic mechanisms were discussed, and an attempt was made to convince her that we believed her pain to be real. During the remainder of her eight-week stay, the patient had little, if any, chest pain, required no narcotics, and was no management problem whatsoever.

This case illustrates how our emotional

reactions to patients and their illness can either hinder or benefit the eventual result of treatment. The patient, being fearful that her physicians and nurses would think the chest pain imaginary, used exaggeration of symptoms and regressive behavior in an attempt to convince them that such was not the case. This was countered by increasing frustration and anger by the medical and nursing staff, to the point that transfer to a new environment and new doctor-patient relationship were necessary in order to help the patient.

Discussion

Not every doctor-patient encounter can be a successful one; not every patient with cancer is cured. Similarly, not every doctor-patient experience will be a happy one; not every patient will have his emotional needs met by a physician (and vice versa). What we have attempted to point out by these two examples is that when the patient seems unreasonable, unmanageable, or uncooperative, a serious attempt should be made to find out why, including a look into the emotional reactions of the medical-nursing staff to that particular patient and his illness.

Each person brings to the doctor-patient relationship his own peculiar attitude toward illness and toward the medical profession. These feelings have been engendered by cultural and socioeconomic backgrounds, personality patterns, and previous life experiences. A situation producing passivity in one patient may cause anger, aggressiveness,

depression, anxiety, regression, or apathy in others. These reactions will, of course, produce different counterreactions in physicians and nurses, depending in turn on their backgrounds. It does little good to treat the "difficult" patient with pompous directives, indignation, or invectives. What is needed is understanding.

Finally, it is important to remember that paramedical personnel take many cues for their own reactions to a patient from the attending physician. No one would consider using the word "cancer" when referring to a particular patient unless the diagnosis was certain. We would make a plea that the same consideration be given for psychiatric designations such as "psychopath," "hysterical," "malingerer," "homosexual," and so on. Such labels conjure up a variety of reactions in the hearers and may do the patient great disservice.

Summary

Two cases have been presented to illustrate how the development of tension between physician (and other medical personnel) and patient can result in a breakdown of communication which may so disrupt the doctor-patient relationship as to impede the successful treatment of the patient. The suggestion is made that a patient's seemingly abnormal responses will appear less abnormal when viewed with greater understanding of the many ways that sick patients, depending on their backgrounds, respond to the stress of illness.

Surgery in the Bible

Surgery in the Bible is limited to two operations: one by the Lord and one by Abraham.

And the Lord God caused a deep sleep to fall upon Adam, and he slept: and he took one of his ribs, and closed up the flesh instead thereof;

And the rib, which the Lord God had taken from man, made he a woman.

The fool maintains an error with the assurance of a man who can never be mistaken: the sensible man defends a truth with the circumspection of a man who may be mistaken. — De Bruix

An Idea Taking Shape

The suggestion of studying medicine was first presented to me, by a lady friend. She once said to me: 'You are fond of study, have health and leisure; why not study medicine? . . . But I at once repudiated the suggestion as an impossible one, saying that I hated everything connected with the body, and could not bear the sight of a medical book.

I had been horrified during my schooldays by seeing a bullock's eye resting on its cushion of rather bloody fat, by means of which one of the professors wished to interest his class in the wonderful structure of the eye. Physiology, thus taught, became extremely distasteful to me.

So I resolutely tried for weeks to put the idea suggested by my friend away; but it constantly recurred to me.

Other circumstances forced upon me the necessity of devoting myself to some absorbing occupation. I became impatient of the disturbing influence exercised by the other sex. . . . But whenever I became sufficiently intimate with any individual to be able to realize what a life association might mean, I shrank from the prospect, disappointed or repelled.

But the struggle with natural repugnance to the medical line of life was so strong that I hesitated to pass the Rubicon, and fought many a severe battle with myself on the subject.

At this time I had not the slightest idea of how to become a physician, or of the course of study necessary for this purpose. As the idea seemed to gain force, however, I wrote to and consulted with several physicians in various parts of the country, as to the possibility of a lady becoming a doctor.

The answers I received were curiously unanimous. They all replied to the effect that the idea was a good one, but that it was impossible to accomplish it.

If an idea, I reasoned, were really a valuable one, there must be some way of realizing it. The idea of winning a doctor's degree gradually assumed the aspect of a great moral struggle, and the moral fight possessed immense attraction for me.

This moral aspect of the subject was increased by a circumstance which made a very strong impression on me. There was at that time a certain Madame Restell flourishing in New York. This person was a noted abortionist, and known all over the country. She made a large fortune, drove a fine carriage, had a pew in a fashionable church, and though often arrested, was always bailed out by her patrons. She was known distinctively as a 'female physician,' a term exclusively applied at that time to those women who carried on her vile occupation.

The gross perversion and destruction of motherhood by the abortionist filled me with indignation, and awakened active antagonism. That the honourable term 'female physician' should be exclusively applied to those women who carried on this shocking trade seemed to me a horror. It was an utter degradation of what might and should become a noble position for women.

Being at the time a reader of Swedenborg, and strongly impressed by his vivid representations of the unseen world, I determined finally to do what I could to 'redeem the hells,' and especially the one form of hell thus forced upon my notice.*

Pheochromocytoma and Ipsilateral Renal Cell Carcinoma

Examination of Important Aspects

GERALD D. MC ELLISTREM, M.D.*
St. Paul, Minnesota

PHEOCHROMOCYTOMA, A GENERALLY histologically benign tumor, causes a malignant hypertension curable by simple extirpation of the tumor, once a diagnosis is established. Thus, awareness of this curable form of malignant hypertension assumes a great deal of importance in our hypertensive workups. Further, this tumor becomes readily identifiable if a minimum of facts are kept in mind. These few facts allow us to quickly evaluate pheochromocytoma as a cause of hypertension and, if it can thereby be eliminated, move on to other causes at once. A discussion of these few facts is the major purpose of this article; a second purpose is the recording of the first case of pheochromocytoma and ipsilateral renal cell carcinoma in the literature.

Clinical Features

Two types of hypertension are recognized: persistent and intermittent. Intermittent hypertension arouses our suspicion from the outset. Typically, the patient will note severe headaches, excess perspiration, and palpitation. Gifford¹ et al. have found that almost all will have at least one of the above complaints. More often than not the patient will be thin and nervous.

Diagnosis

Most patients will be hyperglycemic. Many will have an elevated basal metabolic rate, in spite of a normal protein bound iodine and radioactive iodine uptake. The patient's thyroid is not over-active; the patient simply has hypermetabolism. The intravenous pyelogram is notable for its lack of useful information in many cases.

Physiologic Evidence

The tumor reacts to external stimuli. The most notable is any form of compression;

*Urologist, St. Joseph's Hospital.

therefore, massage of flank and abdomen may cause a rise in blood pressure. Even hyperventilation can cause compression of the tumor.

Provocative Tests

In the normotensive phase the histamine test is used (blood pressure should be below 170/110 for this test). A base line blood pressure is established by performing a cold pressor test: the hand is immersed in ice water and blood pressure is recorded; a diastolic blood pressure rise of 10 to 20 mm. is normal. Histamine 0.05 mg. administered intravenously should produce a 20 mm. systolic and a 10 mm. diastolic rise in blood pressure. Phentolamine (Regitine) must be on hand! In the hypertensive phase, Regitine 5 mg. administered intravenously should cause a 35 mm. systolic and a 25 mm. diastolic fall in blood pressure.

If one becomes suspicious from clinical data, it is worth noting that the above provocative tests take only minutes to perform.

Confirmatory Chemical Tests

The measurement of the 24-hour-free urinary catecholamines* (epinephrine and norepinephrine) and the methylation products of the catecholamines (vanillin mandelic acid and the metanephrines) are most valuable in the diagnosis of this disease.

Diagnosis by Aortography

The aortogram concludes the diagnostic workup. It removes all doubt in questionable cases. More importantly, it localizes the tumor and assists the surgeon by demonstrating the vascular supply. The radiologist will encounter no difficulty with stimulation of the tumor if he keeps an ampoule of phentolamine (Regitine) on hand during the conduct of this examination.

Case Report

A woman was admitted to St. Joseph's Hospital, St. Paul, Minnesota, on 7/28/65 for gross painless hematuria present for the preceding five days.

Past history revealed intermittent hypertension for ten years, often accompanied by severe headache. Palpitation some eight years previously was confused with angina pectoris and resulted in the use of nitroglycerine for a short period of time.

Physical Examination

A white female of 47 was 5'4" and appeared thinner than her 140 lbs. Admission blood pressure was 160/100, but subsequent blood pressures were normal on this admission. Percussion over the flank regions was not painful and no bruit could be heard on auscultation of the flank or back.

Laboratory Studies

The bleeding and clotting times were normal. The fasting blood sugar was 144 mg.%. The sedimentation rate was 10mm/hr. Urine examination was negative for sugar and showed a full field of red blood cells. Urines were negative for acid-fast bacilli and Tbc culture was reported as showing no growth six weeks later.

Diagnostic Studies

The intravenous pyelogram was entirely normal (Figure 1). Cystoscopy on 7/29/65 revealed bloody efflux of urine from the right ureteral orifice and clear urine from the left. Bilateral bulb retrograde pyeloureterograms were normal. Five cc. of 4% silver nitrate were instilled in the right renal pelvis by ureteral catheter, and during the course of the next week the bleeding stopped and the patient was discharged on 8/6/65.

On 9/24/65, the patient was re-admitted to the

Fig. 1 — Intravenous pyelogram showing entirely normal upper urinary tracts.

*See Test Your Word Score Page 687.

hospital with recurrence of gross painless hematuria. On this admission an aortogram was performed and demonstrated a right suprarenal tumor (Figure 2). Note the normal appearance of the kidney on this examination. Blood pressure on this admission was 168/100. Five mg. of phentolamine (Regitine) intravenously dropped the blood pressure to 128/68 in 1.5 minutes. Twenty-four-hour urine for catecholamines showed 570 mcg./24 hours with the normal value being up to 103 mcg./24 hours. The 24-hour urinary vanillin mandelic acid showed 6.5 mg./24 hours with the normal range being 0.7 to 6.8 mg./24 hours.

Operative Findings

Surgical exploration was performed on 9/30/65 with the patient in the supine position. A right subcostal transperitoneal incision was utilized, reflecting the hepatic flexure medially. Dissection of the adrenal tumor was difficult because the tumor infiltrated posterior to the inferior vena cava. A very small portion of the capsule of the tumor could not be excised, since it was fused to the left posterior aspect of the vena cava, between the vena cava and the aorta. The right kidney appeared normal, but because of recurrent bleeding, it was excised along with the adrenal tumor.

Follow-Up of Patient

The postoperative course was one of uneventful

recovery with blood pressures in the normotensive range. The patient was discharged on 10/1/65 and received a course of 20 cobalt treatments to the right renal bed for added insurance. Total dose was 3300 roentgens.

The patient's blood pressure in November 1965, was 120/84 and in December 1965, 130/88. In February 1966, it was 130/80 and in May 1966, 144/94. She was completely without headache or palpitation when last seen.

Pathologic Findings

The Adrenal

Gross appearance revealed a friable, vascular organ. There were necrotic areas and other areas of fibrosis. Microscopic examination showed granular stellate cells. The tumor was well vascularized at the periphery and hyalinized at its center (Figure 3).

The Kidney

The kidney weighed 150 grams. Subcapsular hemorrhage was present in the upper one third. On section, there was a yellow-brown tumor, 2.3 cm. in diameter, and me-

Fig. 2 — Right renal angiogram showing suprarenal tumor but normal kidney. Note especially the upper pole of the kidney where the renal tumor was found.

Fig. 3 — Adrenal tumor showing marked hyalinization. This was an old "burned-out" pheochromocytoma. (Approx. 400×)

dial to the superior calyx, eroding into it. Microscopic examination revealed a papillary pattern of cuboidal cells (Figure 4).

Pathology Diagnosis

(1) Pheochromocytoma of right adrenal gland.

(2) Hypernephroma in right kidney.

Discussion

It is imperative to grasp the difference between a maximally and a minimally secreting pheochromocytoma, as described by Crout² et al., as this helps to understand the variations in secretion patterns of catecholamines, vanillin mandelic acid, and the metanephrines.

In the maximally secreting tumor the free catecholamines are converted directly within the tumor to vanillin mandelic acid and the metanephrines (the methylated metabolites of catecholamines); therefore, in the maximally secreting tumor the free catechol-

amines may be normal and the vanillin mandelic acid or the metanephrine values are abnormally high. Moorhead³ et al. have found the metanephrine (methoxycatecholamine) variations to be more reliable than vanillin mandelic acid measurements when free catecholamines are normal.

However, in the minimally secreting tumor the free catecholamines are not being methylated within the tumor and are, therefore, elevated. The vanillin mandelic acid and metanephrine values may be normal.

The case report presented here is one of a minimally secreting tumor since catecholamines were elevated and vanillin mandelic acid was normal. The morphology of the tumor showing marked hyalinization demonstrates the reason for minimal secretion (Figure 3).

One additional point should be made regarding treatment of this tumor: In the intermittent hypertensive patient there are probably no blood volume changes, but in the patient with persistent hypertension, continuous peripheral vasoconstriction from the catecholamines leads to low blood volume, which must be corrected prior to surgery to prevent uncontrollable shock immediately after removal of the tumor. This correction of blood volume can be achieved by maintaining normotensive levels for two weeks prior to surgery with an adrenergic blocking agent such as phenoxybenzamine hydrochloride (Dibenzylin).

A final point to be made in the present case report is the presence of hematuria from the kidney on the same side as the adrenal tumor. Adrenal tumors do not invade the kidney to cause hematuria. Therefore, a second cause for the hematuria must be found. Despite the failure of the aortogram to demonstrate the 2.3 cm. in diameter renal tumor (Figure 2), a fortuitous decision to remove the kidney was made.

Summary

The importance and ease of diagnosis of pheochromocytoma is presented by discussion of the pertinent clinical and laboratory changes in this disease. Special emphasis is placed on the catecholamines and their

Fig. 4 — Renal cell carcinoma showing its papillary structure. (Approx. 400×)

products of metabolism, since the diagnosis really hinges on these studies. Irreversible shock can occur at surgery. This results from low blood volume which is present in the patient with persistent hypertension through the mechanism of peripheral vaso-

constriction as a result of continuous secretion of catecholamines. Two weeks of an adrenergic blocking agent preoperatively prevents this complication. The first case of pheochromocytoma and ipsilateral renal cell carcinoma in the literature is recorded.

My Get-up-and-Go

How do I know my youth is all spent?
 Well, my get-up-and-go has got up and went.
 But in spite of it all, I'm able to grin,
 When I think of the places my get-up has been.

Old age is Golden, I've heard said,
 But sometimes I wonder, as I go to bed,
 With my ears in the drawer, my teeth in a cup,
 My eyes on the table, until I wake up.

Ere sleep dims my eyes, I say to myself:
 "Is there anything else I should leave on the shelf?"
 And I'm happy to say, as I close the door,
 "My friends are the same — or much, much more".

When I was young, my slippers were red;
 I could kick up my heels right over my head.
 When I grew older, my slippers were blue,
 But still I could dance the whole night through.

Now I am old, my slippers are black;
 I walk to the store and puff my way back.
 But I really don't mind, as I think with a grin,
 Of all the places my get-up has been.

Since I retired from Life's competition,
 I busy myself with Life's repetition.
 I get up each morning and dust off my wits,
 Pick up the paper and read the obits.

If my name is not there, I know I'm not dead;
 So I eat a good breakfast and get back in bed.
 The reason I know my youth is all spent:
 My get-up-and-go has got up and went.

By Mary P. Wilson, Age 83.

The Village Physician and My First Interest in Medicine

It was while I was in Plainfield, before I had studied medicine, that through Dr. Walker I received by baptism in obstetrics. The prospective case was Plainfield's only Magdalene, who lived in a dilapidated house on the outskirts of the town. In preparation Dr. Walker lent me Playfair's *Obstetrics* which, with its classic illustrations, exceeded in interest any detective story. I concealed it in my desk during the day and surreptitiously read its extraordinary revelations at odd times during the school sessions, always expecting that the interesting event which was expected at any moment, would find me unprepared.

On the evening Dr. Walker called for me, he went over the situation as we drove to the house of expectancy, then told me that he had an urgent patient to attend. Would I remain and watch the Magdalene until his return?

Things seemed to me to be developing rather rapidly. It was the first maternity experience for the Magdalene as well as for me, but I expected Dr. Walker to return in time.

To my great relief, at about midnight reinforcements arrived in the person of a thin, aged witch of a midwife carrying a small black bag. About two in the morning we seemed to be reaching a crisis. Convinced that there were fatal complications immediately ahead, I kept close watch on the old woman's face. I was not only completely cooperative but completely nonplussed. Suddenly the old midwife said, "Well, Doc, don't you think we'd better quill her?"

Not knowing what she meant but confident she knew more than I about the procedure, I approved. She took from her small bag a goose quill and a box of snuff. After filling the quill with snuff she inserted one end of it into the patient's nostril, then placed the other end in her own mouth and blew hard. A tremendous sneeze followed and, to my astonishment, the baby arrived precipitately.

Thus encouraged by Dr. Walker, I prepared to enter Wooster Medical School in the spring of 1886.*

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of *MINNESOTA MEDICINE* the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in *MINNESOTA MEDICINE*. We can use many more pictures than we have received in the past.

|| Headache

A Practical Clinical Approach

HAROLD BERRIS, M.D.
Minneapolis, Minnesota

IN ASSESSING patients with headache it is important first to determine which patients require investigation.

Vascular Headache

The most significant is the vascular headache, throbbing at the patient's heart rate. This throbbing may be generalized or local. Vascular headache is due to dilatation of intra or extracranial vessels, presumably due to a histamine-like response. This explains the throbbing nature of the headache in time with the pulse and the increase in headache by bending over, coughing, sneezing, or bowel movement.

Symptomatic vascular headaches are seen with space-occupying lesions such as tumors, cysts, brain abscesses, and hematoma due to local vascular irritation and stretching as well as to increased intracranial pressure. Encephalitis and meningitis also produce vascular headaches, usually with fever. Specific vascular headaches are diagnosed as migraine, Horton's cephalgia, cluster headache, post-spinal headache, postictal headache, temporal arteritis, "seizure equivalent headache," and carotid sheath syndrome.

Migraine

Migraine, by definition, is a unilateral vascular headache, often inherited, which is recurrent and may be preceded by aura. The headache is often tension-triggered and may also be associated with menses due to the tensions concurrent with this, or to the sodium and fluid retention of the premenstrual state. An aura often occurs when intracranial vessels are involved and consists of scintillating scotomata, hemianopsia,* hemihyesthesia or hemiparesis of ten to fifteen minutes duration due to localized vasospasm which precedes the stage of vasodilatation producing the headache. The symptoms, with different episodes, may shift from side to side, and this is reassuring, since if all

*See Test Your Word Score Page 687.

the attacks remain on one side, particularly with aura, consideration of vascular malformation such as arteriovenous malformation or aneurysm must be considered. Unruptured aneurysm can produce migraine syndrome even in the absence of localized cranial nerve palsy. It is said that twenty per cent of patients with migraine have a vascular anomaly.

Therapy of migraine is preferably of a long-term nature. For the actual headache, large doses of aspirin may often help more than opiates. At times, especially with definite tension triggering of the headache, Mebaral 100 mg. and Meproamate 400 mg. allow the patient to sleep off his headache. Long-term therapy such as the use of sedatives, tranquilizers, Dilantin in anticonvulsant doses or Sansert may be helpful.

Horton's Cephalgia

This often occurs at night with conjunctival congestion, tearing and nasal stuffiness and discharge on the side of the headache with visible distention of the superficial temporal artery. Therapy is as above. One may have to try histamine "desensitization."

Cluster Headache

This syndrome is a vascular headache which derives its name from the temporal relationship of the headaches; that is, they occur in clusters or series with periods of freedom from headache of varying length. At times patients describe a seasonal incidence of headaches. Facial pain may occur as a concomitant.

It is said that an ergot drug is almost specific for this syndrome by aborting the series of headaches. It is given twice daily for five days until the headache has cleared and then used on a similar basis intermittently. If the clusters are frequent, then Sansert may be used on a regular basis, but this has the disadvantage of cost as well as the possible side effects of gastrointestinal distress and the recently described complication of retroperitoneal fibrosis.

Post-spinal Headache

This is actually a low spinal fluid pressure headache which on rare occasions may occur

spontaneously, but usually follows spinal tap. In the latter, it is postulated that there is a continued leak of cerebrospinal fluid through the dura at the needle puncture site. Characteristically, the headache is severe and throbbing and is present in the upright position and always relieved virtually completely by lying down. The symptoms last up to two weeks and the treatment consists primarily of bed rest, but vasodilators such as Cyclospasmol and five per cent CO₂ inhalation for five minutes each hour may increase the cerebrospinal fluid pressure. Often where there is an attendant anxiety associated with a spinal tap, one may see tightness develop in the nuchal muscles much as in the muscle contraction headache, and these patients may develop posterior cervical pain which should be treated with heat.

Temporal Arteritis

Temporal arteritis usually occurs in patients over the age of 60 and may be bilateral. The headache is vascular and quite persistent. The superficial temporal artery may or may not be red, swollen or tender. Sedimentation rate is usually elevated. Early diagnosis is important, so that one may prevent the possible complication of blindness. Steroid medication for a six-month period is recommended.

Carotid Sheath Syndrome

Vascular headache and facial pain occur in this condition, at times with the facial pain predominating. The diagnosis is made by demonstrating tenderness over one or both carotid vessels. The condition tends to be self limiting in six to eight weeks; but if the pain is severe, the use of steroids orally may produce fairly prompt relief.

Postictal Headache

This consists of typical vascular headache, often severe following major seizures. Of course the therapy must be directed towards adequate seizure control, but one may use the usual methods of pain relief.

Seizure Equivalent Headache

This headache is more difficult to docu-

ment, but the suspicion of this type of headache is important since therapy is often very effective. The patient complains of vascular headache. On occasion, he may awaken at night with a vascular headache. True vertigo is sometimes present as a symptom unassociated with the headache. There is often a past history of poliomyelitis, rheumatic fever, infectious mononucleosis or some other encephalitic process or a past history of head trauma. Electroencephalogram frequently shows a small amount of random sharp wave activity which may be insufficient to characterize the tracing as abnormal; but occasionally paroxysmal electroencephalogram disturbances are seen. Many patients develop their symptoms after what appears to be relatively insignificant head trauma. Because of the frequent occurrence of electroencephalogram changes and because of the excellent response to Dilantin in anticonvulsant doses it is postulated that the patient may be having subclinical seizures and that a vascular headache follows as a postictal phenomenon.

Tension Headache

The next most important headache because of its frequency is tension headache; or, to use newer terminology, the muscle contraction headache. This typically begins nuchally with tightness, aching and burning and often progresses to a generalized non-specific variable head pain. There is often interscapular pain and burning. Muscle contraction headache is associated with increased activity of the nuchal muscles demonstrated electromyographically. There is diminution of the true resting state. These headaches are tension-triggered, although the patient may or may not be aware of the tension, since frequently recurring tension may be a function of the patient's personality makeup rather than environmental stress. Many patients with this form of distress never seek medical attention, especially if they are aware of the mechanism of the headache. Care must be taken with this type of headache to consider beginning subarachnoid hemorrhage. This characteristically produces vascular headache, but it also produces symptoms due to irritation of the bas-

ilar meninges and therefore causes upper neck pain and ultimately neck stiffness. Another cause of posterior headache is involvement of the greater occipital nerve either spontaneously or due to involvement of the C1-2 nerve roots, which is commonly seen after flexion extension injuries of the cervical spine. Nuchal rigidity of meningeal origin may be differentiated from that of cervical spine or muscular origin by testing the rotation of the neck. Meningeal irritation produces pain and limitation of range of motion with neck flexion, while neck disease produces pain and limitation with rotation as well as with flexion as a rule. If the patient is seen in the throes of a muscle contraction headache, one can often confirm this by twenty to thirty seconds of firm compression of the upper posterior cervical muscles which will produce transient relief of the headache.

Therapy for the individual muscle contraction headache is unrewarding unless it is infrequent. One may give opiates, Darvon, etc., but these are contraindicated in frequently recurring headaches. The therapy of choice, especially with moderately frequent headaches, is daily treatment with Mebaral grains $\frac{3}{4}$ to $1\frac{1}{2}$ grains three times daily, alone or in combination with nicotinic acid 50 mg. three times daily before meals; or with Librium 10 mg. three times a day. This is continued for two to six months and gradually tapered. Aspirin is a useful drug for treating the individual headache. In intractable cases or when one suspects significant psychiatric problems, psychotherapy may be helpful.

Psychogenic Headache

This type of headache is more akin to a hysterical symptom, in which the patient complains of a tight band-like pain around the head with severe pain like a tourniquet or belt being twisted about the head. Other patients complain of a big or heavy head, as if the head is too heavy for the neck or is going to explode. Often these patients will complain of sensitivity to light and of being distressed by noises. The mechanism of this headache is difficult to explain pathophysiologically. These patients often have severe,

frequent, or constant headache. Symptomatic therapy again might be valuable with daytime sedatives or tranquilizers, but more often in these cases one will have to resort to psychiatric referral.

Headache of Pituitary Adenoma

This is orbital, frontal and temporal, and has no particular distinguishing characteristics. It is therefore quite treacherous since it is an early symptom of pituitary gland enlargement. The headache of pituitary tumor is due first to pressure on the diaphragm sella. Afterward the tumor may rupture through the diaphragm and produce a different kind of headache, that of increased pressure or a vascular headache due to local blood vessel changes. Obviously the therapy must be directed to making an accurate diagnosis and then treating the tumor of the pituitary.

Ice Cream Headache

This headache is a referred vagal reaction

to cold and is merely mentioned since it is of no clinical significance.

Miscellaneous Headaches

At times, facial pain is associated with headache; or patients may interpret facial pain as headache. Sinus headache is usually associated with facial pain, but it may also produce vascular headache as in ethmoid sinusitis with inflammatory involvement of the adjacent meninges. Ocular origin of headache is common. Pain due to refractive error is not present in the morning but increases with eyestrain and is present later in the day. The headache of glaucoma, especially acute glaucoma, may produce some problems in differential diagnosis. Trigeminal neuralgia is a recurrent lancinating severe pain, almost always unilateral, the location depending on the branch involved. Herpes zoster of the fifth or seventh cranial nerves may produce head pain as long as two weeks prior to the appearance of the zoster lesion, and for this reason may be difficult to diagnose accurately.

Filling Out Blanks

Voltaire defined a doctor as a man who introduced substances he did not quite understand into bodies he understood even less. This was not meanly said: Voltaire was a lifelong sick man who loved his doctors and owed them eighty-four years of remarkable activity. But for his sake and theirs he reminded them from time to time that they were limited, not absolute, monarchs. . . . The temptation to act like Jehovah must be great, and it is not always resisted, but that is a risk the public must run. It is inherent in the situation.

The sick person wants to believe the doctor omnipotent, and this very confidence helps. But was it not rather the old-fashioned physician who best knew how to enlist that aid? Modern specialization works in the opposite direction. Right now, one physician in three is a full-time specialist, and what he wants to know is "Have you got my disease?" You hope you have, so as to put an end to the shopping around and the interminable waiting and filling out of blanks. You undergo all the tests again at ten to fifteen dollars each — none of the earlier ones are acceptable to the new man — and he puts you through his routine, eager to *finalize the case*.

Jacques Barzun: *When the Doctor Is a Pill* (in *God's Country and Mine*) 1954

*Strange, is it not? that of the myriads who
Before us pass'd the door of Darkness through,
Not one returns to tell us of the Road,
Which to discover we must travel too.* — Omar Khayyam (?-1123)

|| Fluorescence

Selected Medical Aspects

WILLARD C. PETERSON, JR., M.D.*
Minneapolis, Minnesota

IN 1942 COONS and his colleagues reported a method whereby antibody could be conjugated to a simple chemical compound, such as fluorescein, without altering its ability to react specifically with antigen. Following this application there has been an ever increasing interest in the use of fluorescein labeled antibody as a method for identifying antigen-antibody reactions as well as localizing the sites of such reactions. In addition, other applications involving the property of fluorescence have been developed in recent years which have added valuable methods for identification and tracing both in clinical practice as well as in research. The present paper will discuss briefly some of the current applications of fluorescence to medicine. However, no attempt has been made to cover the entire scope of this interesting subject.

Fluorescence

Briefly, fluorescence is the emission of light by molecules or atoms following excitation through absorption of light. This phenomenon occurs when a molecule absorbs a quantum of radiation of sufficient energy to alter its electronic distribution. The molecule is then said to be in the excited state. If the excited state is stable and degradation does not occur by collision of the molecule with one of its neighbors, the molecule will return to its ground state by emitting fluorescent radiation. Molecules which possess a conjugated system of double bonds usually have relatively stable excited states and therefore have the characteristic of fluorescence. An example of this type of molecule is fluorescein. In addition, these molecules have small differences between absorption and emission wavelengths due to the small internuclear distance between their

*Clinical Instructor, Division of Dermatology, University of Minnesota Hospital, Minneapolis, Minnesota.

Requests for reprints address to 345 Medical Arts Building, Minneapolis 55402.

ground and excited potential energy curves. As a rule the wavelength of the fluorescence or emitted radiation is greater than the absorption or exciting radiation. This is referred to as Stokes' law and is illustrated by fluorescein whose main absorption peak is at 490 m μ and its fluorescence emission at 525 m μ .

Most fluorescent procedures in medicine are relatively simple to perform, involving either direct viewing or simple staining techniques. A difficulty is the high initial cost for the fluorescent microscope with its assorted filters, but many sources are available for adapting existing microscopes to this usage, thus reducing the cost considerably.

Before discussing various techniques employing the application of fluorescent dyes in biological preparations it would seem appropriate to mention several types of natural fluorescence which may occur without prior treatment or application of a fluorochrome.

Tissue Autofluorescence

The majority of human tissues fluoresce blue to bluish-green when viewed with a fluorescent equipped microscope. This fluorescence becomes more intense with the age of the preparation. In addition, various forms of fixation will alter this fluorescence. It is interesting to note that not all organ systems fluoresce with the same intensity; brain and renal tissue have a very strong autofluorescence. The nature of tissue autofluorescence is not understood, many agents both natural as well as drugs having been suggested as contributing to this phenomenon. Vitamin A has been suggested as a possible source of the greenish autofluorescence of skin.² However, no one substance is known to be primarily responsible for autofluorescence in normal tissues.

Porphyrin Molecule

Autofluorescence other than blue may be present in certain pathologic states, most notably porphyria. Runge and Watson demonstrated red fluorescence of the porphyrin molecule in the skin of patients with porphyria.³ Interestingly, this fluorescence was less intense on light-exposed areas of human skin. This fluorescence may also be demon-

strated in normoblasts of patients with porphyria erythropoietica and in the liver in porphyria cutanea tarda. In porphyria if the concentration of uroporphyrin is large the urine will fluoresce when acidified and viewed with a suitable ultraviolet light source.

Various Fungi

This by no means exhausts the list of normal and abnormal states in which so-called autofluorescence is present. It should be mentioned that not all fluorescent tests involve rare diseases or expensive apparatus. The use of a Wood's light [an ultraviolet lamp with a nickel oxide filter producing a wavelength of approximately 3650 Å] has been used for many years as an aid in the diagnosis of various fungus diseases. *Tinea capitis* caused by *M. audouini* and *M. canis* will show this type of fluorescence. *Tinea versicolor* with its yellowish fluorescence and *erythrasma* with a coral red fluorescence are further examples.

Fluorescent Antinuclear Antibody

Antinuclear antibodies found in the IgG, IgA and IgM fractions of serum globulins have been identified in an ever increasing number of diseases demonstrated with the indirect Coons technique. In brief, this procedure involves applying sera, suspected to contain antinuclear antibody activity, to a cellular source of nuclei. After a specified incubation period the cells are washed and fluorescein-labeled antihuman globulin, if human sera are being tested, is applied. This is again incubated, washed and viewed with a microscope which has been fitted with an ultraviolet light source, darkfield condenser and proper filters. If the test is positive one views nuclei with human antibody globulin attached and to which is united antihuman globulin antibody which has been conjugated to fluorescein. It can be seen that the human globulin antibody has a dual function. First it functions as antibody and then as an antigen for the fluorescein-labeled antihuman globulin. This method has been appropriately called the "sandwich technique." This is also known as the indirect method as contrasted with the direct technique. In the

latter, the antisera under study are conjugated to the fluorescein. At present the "indirect" technique is in more common use, for it appears to have greater sensitivity. However, it involves more steps and is harder to control than the "direct" method. The fluorescent dye most often used in this country is fluorescein isothiocyanate, whose molecule has a peak absorption at 490 $m\mu$ and a fluorescent emission at about 525 $m\mu$. Its protein conjugates give off an apple-green fluorescence. It is readily available commercially, both in a free and in a conjugated form. By conjugation is meant the joining of the fluorochrome to the protein (antibody). This must be a stable bond for success, not a simple dye-protein adsorbate which tends to dissociate. The degree to which conjugation affects antibody activity appears to vary with the basic nature of the antibody molecule, its reactor sites, and with other factors.

When viewing these preparations one uses a microscope equipped with an ultraviolet light source and a darkfield condenser. If positive, there is bright apple-green fluorescence observed in the nuclei of the cells being used. In addition, the nuclei appear somewhat enlarged or swollen. In a negative test only the outlines of the nuclei will be seen. There are several commonly observed patterns of nuclear fluorescence: homogeneous, speckling, and nucleolar. In addition, a form in which the fluorescence is found beyond the nuclear membrane has been reported. This last type is stated to be characteristic for systemic lupus erythematosus. At present it seems unwarranted to place emphasis upon the various nuclear patterns in regard to specific diagnoses.

Fluorescent Treponemal Antibody Test

This method makes use of the indirect Coons technique to test for the presence of antibodies directed against *treponema pallidum*.^{*} It is performed in essentially the same manner as the fluorescent antinuclear antibody test with the exception that *T. pallidum* is the antigen instead of nuclear material. If the patient's serum is positive the treponemes will fluoresce and are therefore eas-

ily identified. This procedure has definite advantages over such tests as the *treponema pallidum* immobilization test. First, it is less expensive, not requiring live treponemes, and secondly, one does not have to be concerned with the exact morphological identification of the treponemes. This test is presently referred to as the fluorescent treponemal antibody-absorption test. In this procedure a water soluble extract of Reiter treponemes is employed to remove nonspecific antibodies shared by *T. pallidum* with nonpathogenic treponemes. This has increased the test's specificity.

This discussion by no means exhausts the list of applications of the indirect fluorescent method of protein tracing. It has been applied to studies of bacteria, viruses, and fungi with varying degrees of success and in many instances, equivocal results.

Acridine Orange

Malignant cells show an increase in ribonucleic acid within their cytoplasm as well as large amounts of desoxynucleic acid in their nuclei. The acridine orange method of rapid staining is based upon this fluorochrome's affinity to stain both these proteins. In an alcoholic solution acridine orange binds to nucleic acid by electrostatic linkages and van der Waals forces. When viewed with a fluorescent microscope the cytoplasm of a malignant cell stains brilliant red, while the nucleus stains green to yellow.

Considerable controversy exists concerning the interpretation of findings with this method. Apparently dye concentration as well as pH are important factors. Only with low concentrations of acridine orange do the nucleus and cytoplasm stain differently.

Raskin⁴ in studying 446 cutaneous tumors with acridine orange was able in most instances to differentiate malignant from benign lesions. Due to the fact that many benign cells also show fluorescence to some extent with this method, the examiner must discern whether the cells show abnormal morphology. Therefore, in this method not only fluorescence but morphology must be ascertained regarding the question of malignancy. The acridine orange method has been

^{*}See Test Your Word Score Page 687.

applied to cervical smears and various body fluids.⁵ In the hands of an experienced examiner it does provide a method of rapid screening for malignancy in cytological specimens. However, in all cases the final diagnosis of malignancy rests with the pathologist.

Tetracycline Fluorescence

Tetracycline tends to localize in certain tissues such as teeth, bone, tumors and ulcers, fluorescing a brilliant yellow when viewed with an ultraviolet light source.

The deciduous teeth of children may be stained with tetracycline given to the pregnant mother during or after the fifth fetal month, an effect apparently related to total dose of the drug and not to the duration of therapy.⁶ The color of the teeth will vary from yellow to a dirty brown. Under Wood's light, teeth so affected will fluoresce yellow. The drug apparently forms a chelate with calcium, and because calcium turnover in teeth is slight, this staining remains indefinitely.

Growing or calcifying bones show an uptake of tetracycline, which can occur in normal and abnormal bone as well as in osteosarcomas. It has been demonstrated in areas of ectopic ossification as well as ossified areas of osteosarcomas.^{8,9} Following a single dose in dogs, tetracycline may remain in bone up to one year.⁷ Due to the fact that there is a turnover in bone calcium, this drug will gradually be lost from bone. Bone which has been formed prior to tetracycline administration has only a blue-autofluorescence while bone formed in the presence of tetracycline will fluoresce yellow. This fluorescence tends to appear in any tissue when calcification is occurring.

Various tumors may show fluorescence following tetracycline administration. This localization of tetracycline has been demonstrated in cutaneous as well as internal malignancies. In 1957 Rall et al.¹⁰ demonstrated that carcinomas would fluoresce under ultraviolet light if the patient had received tetracycline. Since then, tumor affinity for this drug has been demonstrated in many ma-

lignancies. Berk and Kantor¹¹ used tetracycline fluorescence of gastric sediment as a test for carcinoma of the stomach. Lipnik¹² reported a method of rapid screening of cutaneous malignancies which involved the application of a demethylchlortetracycline solution to the suspected lesions. A yellow-green fluorescence resistant to 4.9% trichloroacetic acid develops in the lesion when viewed with ultraviolet light. The author has found this drug to cause fluorescence in basal cell epitheliomas, squamous cell carcinomas, and malignant melanomas when patients have had as little as a single 1000 mg. oral dose the day prior to removal of the tumor. With respect to squamous cell carcinoma one must interpret these results with caution, for this tumor may show autofluorescence without prior tetracycline administration.¹³ This fluorescence is restricted to the necrotic ulcerated areas of the lesion.

Loo et al.¹⁴ found that in mouse tumors the fluorophore is apparently a tetracycline-peptide complex that dissociates readily in acid media. Dubuy and Showacre¹⁵ reported that tetracycline combined specifically with mitochondria of animal cells. The exact nature or mechanism of tetracycline's affinity for tumor tissue has not as yet been elucidated. Many of the reports concerning this drug's affinity for tumor tissue have been conflicting and any practical application must await further investigation.

Thioflavine-T and Amyloid

The demonstration of amyloid by histochemical techniques is often difficult. Methods in common use include metachromasia with Congo red and crystal violet, dichroic* birefringence with Congo red, and the fibrillar structural pattern viewed with the electron microscope. Results obtained with Congo red and crystal violet are often equivocal. Both methods may produce false negative as well as false positive results. In addition, the crystal violet method must be viewed soon after preparation, for fading of the reaction occurs rapidly. Of the methods mentioned thus far, Congo red dichroic birefringence is most specific and produces the fewest false-positive results.

Another method for amyloid demonstra-

*See Test Your Word Score Page 687.

tion has recently been described by Vassar and his associates, involving the fluorochrome thioflavine-T.¹⁶ Amyloid, when stained with this substance and viewed with a fluorescent microscope, will fluoresce brilliant yellow. This technique has certain advantages over the other methods for demonstrating amyloid deposits. First, it is far more sensitive and gives results more consistently positive.¹⁷ Secondly, the deposits are more sharply defined with this method and much smaller deposits may be identified. False positive results do occur, such as the staining of keratin; however, these are usually easy to identify. This method is of definite value in demonstrating amyloid, especi-

ally in rapid screening. It is best, of course, to also use one or more of the other methods in conjunction with thioflavine-T.

Conclusion

Many new techniques involving fluorescence have been introduced in recent years. Numerous other fluorescent applications of interest exist, such as fluorescein and rhodamine B for reticular fibers and osteoid tissues, acriflavine for elastic fibers, and acridine orange or Atabrine for mucin, to mention just a few. The use of fluorescent microscopy has provided an interesting as well as helpful tool in both routine pathologic diagnosis and research.

The only freedom which deserves the name is that of pursuing our own good in our own way, so long as we do not attempt to deprive others of theirs, or impede their efforts to obtain it. Mankind gains more by suffering each other to live as seems good to themselves than by compelling each to live as seems good to the rest. — John Stuart Mill

What the future has in store for you depends largely on what you place in store for the future. — Kalends

Power of Will

Eight years ago I decided to give up smoking, as I had always smoked rather too much. Although I could stop it for a short time, at the end of, say, a month I was only too glad to get back to smoking again, and suffered from deprivation symptoms in the meantime. I therefore decided to try my own method. Having burnt my tobacco pouch and pipe, I leant back in my chair, relaxed my muscles, and thought of sleep — starting with the extremities, fingers, toes, hands, and feet, and reinforcing the relaxation by deep breathing. When in a thoroughly relaxed state, I silently affirmed to myself 'I shall never smoke again; it means nothing to me. I shall feel no desire for it, no need. I shall never want to smoke again.' I thought that for a few seconds and then went to bed. Next morning I did not even think about smoking, and have never smoked from then until now. By using this method I had destroyed the desire and need for smoking. It is a method, not of supplanting the will but of supplementing it. Indeed, I would go farther and say that it is a form of mind training whereby one reaches a completed will.*

*William Brown, D.M., D.Sc., F.R.C.P.: *Mind, Medicine and Metaphysics*, London, 1936.

Hippocrates*

Hippocrates' COLLECTION contains the following case history: a superb example of terseness of expression and precision of comment:

"In Abdera Pericles was seized with acute fever, continuous and painful; much thirst; nausea; could not retain what he drank. There was slight enlargement of the spleen and heaviness in the head.

First day. Epistaxis (bleeding) from the left nostril; the fever, however, increased greatly. Copious urine, turbid and white. On standing it did not settle.

Second day. General exacerbation (in symptoms); the urine, however, had consistency, but there was some sediment; the nausea was relieved and the patient slept.

Third day. The fever went down; abundance of urine, with concocted and copious sediment; a quiet night.

Fourth day. About mid-day a hot, violent sweating all over; crisis; no relapse."

It is a great misfortune neither to have enough wit to talk well nor enough judgment to be silent. — La Bruyere

*Look round the habitable world; how few
Know their own good; or, knowing it, pursue. — Juvenal*

Triamcinolone Hexacetonide*

Sublesional Use Of

CARL W. LAYMON, M.D.**
WILLARD C. PETERSON, JR., M.D.**
Minneapolis, Minnesota

DESPITE THE LARGE number of steroid products now available, there are relatively few experiments published in the literature concerning their intralesional or sublesional use in the treatment of various dermatologic disorders. This route of administration has several obvious advantages. Compared with oral administration, sublesional injection allows the effective use of steroids in much smaller doses and thus greatly reduces the risk of the well-known systemic side effects of these compounds. When compared with topical applications, sublesional use avoids the variations in the ability of the compound to penetrate the skin and the resultant variability of clinical results. It has also been shown that many skin diseases that do not respond to topical steroids will respond to intracutaneous injections.²

The clinical response attained from the application of steroids to dermatologic lesions depends largely on the local concentration of the drug and the length of time it remains deposited at the site of injection. In the past, best results have been reported from the use of the acetate, diacetate, and tertiary butyl acetate of prednisolone and triamcinolone.

In 1961, J. L. Hollander presented evidence that triamcinolone acetonide tertiary butylacetate (hexacetonide) suspension, when assayed by intra-articular injection in arthritic patients, more than doubled the duration of effective relief in the majority of patients tested.¹

These studies and others led to the experimental use of this compound in dermatologic disorders by injection directly into or

immediately under the lesions. It is the purpose of this communication to report such a trial in 45 patients who had not had previous therapy with similar agents.

Materials and Methods

Patients for this study were selected for the presence of a variety of cutaneous diseases (Table 3). No requirements as to age or sex were stipulated. However, ages ranged from 19 to 75 years, as shown in Table 1. There were 20 males and 25 females in this study.

Dosage was based on the sublesional administration of approximately 2 mg. of triamcinolone hexacetonide per square inch of lesion. In all except one instance only one injection of 1 to 5 mg. was required for each lesion. One patient with lichen chronicus simplex (circumscribed neurodermatitis*) was given a second injection one month after the first. No other treatment was administered during the period of study and patients were observed at weekly intervals for a minimum of one month. The results were evaluated by the following criteria: the response was considered to be "excellent" when there was complete clearing of the lesions, "good" when there was less than total clearing but more than half, and "fair" when there was some improvement but more than half of the lesion remained. The results were noted independently by each of the two investigators.

Sixty-one percent of the evaluations were made in patients treated for only one lesion, 22% had two lesions treated, and 16% had three or more lesions treated. Doses ranged from 1.0 to 5.0 mg. and averaged 2.0 to 2.8 mg. per patient (Table 2).

study, three of the tabulations (Tables 2, 3, and 4) are based on the premise that those patients treated on more than one occasion constituted a separate evaluation of the efficacy of the drug. This situation occurred in three patients, two of whom were each treated on two different dates, and one who was treated on three different dates, making a total of 49 evaluations in 45 patients.

Ten discrete disease entities were diagnosed. Of a total of 49 observations, 14 or 28.5% resulted in an excellent response, 28 or 57.5% were judged good, and seven or 14.3% were fair or without change (Table 3). The majority of patients were treated for psoriasis or localized neurodermatitis. In both of these groups 90% of the evaluations showed excellent or good results. It is interesting to note that all evaluations were made independently by each of the two investigators with a high degree of correlation.

During these 49 patient evaluations, 86 lesions were treated. Table 4 summarizes these clinical responses. In 88.2% of the lesions treated, results were judged to be excellent (30%) or good (58.2%).

Duration of Response

During each patient evaluation the time of onset of effective response and the duration of this response were noted. In those patients with excellent and good responses, the onset of improvement was noted within two weeks of the administration of the drug. When pruritus was present, definite relief occurred frequently within 24 hours of

treatment. There followed a gradual diminution of swelling, erythema, and scaling, and a reduction in the size of the lesion.

In all but three cases, the drug was still effective at the end of the study (for the number of days tabulated in Table 5) and there was no regression of the lesions during this time. In one patient the effects of one injection lasted only two weeks. However, another injection given a month later produced good results that still persisted at the termination of the study two months later. Thirty-four of the 45 patients (75.5%) had effects lasting for 35 days or more.

Side Effects

The observed side effects involved three patients, each of whom developed a sterile abscess, and one in whom there was a hemorrhagic reaction at the site of the injection. All of these subsided uneventfully and did not appear to interfere with the efficacy of the drug. In addition, three instances of mild cutaneous atrophy occurred. One patient developed two of these areas of atrophy which have remained for six months. No systemic reactions were seen.

Discussion

The course of psoriasis, neurodermatitis and other dermatoses is frequently unpredictable. Spontaneous remission or exacerbation is not uncommon. Although controlled studies are usually desirable, it is necessary to assess the disadvantages of various types of controlled studies when evaluating the treatment of these diseases.

Placebo Controls or Untreated Controls

Both psoriasis and neurodermatitis, which constitute the majority of cases treated in this study, are influenced strongly by psychological factors. Thus, in diseases of this nature, a prominent placebo effect, or spontaneous changes in untreated patients, can be predicted.

Paired Comparisons

When treating some lesions in one patient with an active drug and other lesions with a placebo, the results may be undecisive due

*One patient had no response.

to the effect of systemically absorbed drug on the placebo-treated lesions.

Crossover Treatment with Two Drugs

This study design is complicated by two factors: (a) the possibility of an effect of residual drug on the second phase of the trial, and (b) the lack of a true base line for comparison (e.g., the disease is not in its original, untreated state after the administration of the first course of treatment). In both cases the second phase of the trial is difficult to evaluate because of the existence of a previous course of treatment.

The disadvantages of an uncontrolled study are well known. However, an effort was made to draw valid conclusions by creating objective criteria for the evaluation of the clinical results, and by having these results judged independently by two investigators.

Summary and Conclusions

Forty-five patients were treated for a variety of cutaneous disorders by the sublesional injection of triamcinolone hexacetonide. Within two weeks of treatment, the majority of patients had excellent or good results which lasted for 35 days or longer. With doses limited to approximately 2 mg. per square inch of lesion, local side effects were minimal. Sterile abscess, hemorrhagic reaction, and mild cutaneous atrophy occurred at the site of injection in 1.5% of the patients. These reactions were mild in degree of severity and did not interfere with the efficacy of the drug. All of these local reactions were transient with the exception of the mild cutaneous atrophy which persisted for approximately six months at two sites in one patient. However, these appeared to be slowly subsiding. There were no systemic reactions noted in any patient in this study.

Nature's Insuperability

In the inner cavity of the larynx there is a structure of peculiar formation, which we have already shown to be the principal organ of the voice. It resembles the mouthpiece of a reed-pipe, especially when seen either from above or from below. Instead, however, of comparing the glottis with the tongue of reed instruments, it would be more appropriate to compare them with the glottis. For the works of Nature are both earlier in time, and more perfect in construction, than those of art; and, as the glottis is the work of Nature, while the reed-pipe is the production of art, it is possible that the latter might have been made in imitation of the glottis by some clever artist, able to understand and copy the structure of natural objects. — Galen

In the problems which the Almighty sets his humble servants things hardly ever happen the same way twice over, or, if they seem to do so, there is some variant which stultifies undue generalization. The human mind, except when guided by extraordinary genius, cannot surmount the established conclusions amid which it has been reared.

I Remember. I Remember

*"How dear to this heart are the scenes of my childhood
When fond recollection presents them to view!"*

Samuel Woodworth

IT HAS OFTEN occurred to me that one of the most valuable, yet least recognized natural defense mechanisms of man is the ability of the brain to store away countless memories — good and bad — and after doing so to be able to eliminate from immediate consciousness those recollections which are unpleasant, thus allowing him to dwell upon happy memories of the past. Were it not so, life would be intolerable; we should either become misanthropes or go mad.

World War I

Thus it is that recollections of our youth, despite hardships, assume a roseate hue. In March 1917 the Russian Revolution began and in April the United States entered World War I, a titanic struggle which was to become the greatest military holocaust in history up to that time. But it is easier — and therefore, more pleasant for me to recall that during 1917-18 I was a senior in Medical School at the University of Minnesota, that we students were beginning to see patients and feel a little like physicians, and that our work-load of lectures and classes had suddenly become much lighter. The relief was so great that I was able to scratch a long-standing itch by joining the Masquers and other drama groups on the campus. I had previously taken some courses in Speech

with Dr. Frank Rarig and as a result of these experiences became convinced that every university student, as a potential leader in his work or in his community or in both, should have a substantial amount of training in the art of public speaking.

The Influenza Epidemic

But this welcome extracurricular freedom was not to last long. Some time during 1917 an ominous cloud, aside from but concurrent with the war, appeared in the East. An outbreak of influenza, more insidious and destructive than any epidemic of modern times, began to roll toward the United States from abroad. By late 1918, when it finally began to subside, the disease had killed an estimated twenty million people throughout the world, including 548,000 members of the American Armed Forces.

In June 1918 my medical class graduated and all the men were immediately inducted into military service, receiving the new degree, "Bachelor of Medicine." After passing the State Board examinations it would have been entirely legal for us to practice medicine in Minnesota (although none of us did) as "Mr." rather than "Doctor" Jones, as was the case with many physicians and surgeons in England for a long time.

Some of the graduates joined Base Hos-

pital 26 for service in Europe. Arthur Law was head of the surgical section and S. Marx White of the medical division of this unit, these graduates having been given their M.D. degrees before leaving. Others were assigned to duty as internes; of these a number, including myself, went to the then Minneapolis (now Hennepin County) General Hospital and received their M.D. degrees upon completion of their internships in 1919. Among others in the Base Hospital group were E. D. Anderson (Ted became ill after some years in the practice of pediatrics and moved with his family to Switzerland), Egbert Borgeson, Woodard Colby, Harold Diehl, David Kadesky, Elmer Lundquist, Donald McCarthy, Albert M. Snell and Carl Swendseen; in the General Hospital group were Ed Norris, Sam Weisman, Stillman Hathaway, William Peyton, Laurits Ylvisaker, Anderson Hilding, George McGear, Morris Nathanson, C. L. Roholt, et alia.

The General Hospital was literally filled with desperately ill influenza cases. Rooms, wards, halls and corridors were crowded with beds. Despite our best efforts, the death rate, especially from pneumonia, was high.

Armistice Day

During all this time the war was grinding on. In January 1918, President Wilson made his celebrated 14-Point address to Congress, calling among other things for the self-determination of nations, the removal of economic barriers and the establishment of a League of Nations. In July 1918, Czar Nicholas and his family were assassinated. Finally, on November 11, 1918, the Armistice was signed and World War I ended. What a day to remember!

Unmarried Interns

Once again, with the war over, and the epidemic subsiding, we could begin to relax. Many of us had struggled so hard to put ourselves through Medical School, financially and scholastically, that we had had time for almost nothing else but work. Now, suddenly we discovered girls — pretty, bright nurses in their crisp blue and white uniforms. But there was one great obstacle: student nurses were forbidden to have social

contact with members of the attending or interne staff, except at occasional dances in the Nurses' Home. So what could be more natural than that nurses and internes meet elsewhere; if some of us internes were a little awkward and lacked skill, the girls didn't seem to mind. It must be remembered that in those days there were practically no married student nurses and very few married internes.

Well, meet they did, and as a result many romances and marriages developed. A few come to mind: Verne Walsh and Larry Doyle; Veda Newman and Nels Gunderson; Ruth Daly and Frank Hirshfield; Blanche Rucker and Hillard Holm; Ann Dahl and Joe Neal; Mary Dean and Virgil Schwartz.

In 1917, and for some years before and after, there were staff problems at the General Hospital. There were two services in almost every department: the A service was staffed by men with University affiliation, the B service by men without University connection. If memory serves me well, the head of A medicine was Henry Ulrich, the head of B medicine, Soren P. Rees. The head of A surgery was Arthur Mann, the head of B surgery, A. E. Booth. Most other departments had similar dichotomous arrangements. A good deal of disharmony was thus engendered and continued for years until a sort of detente developed, leading eventually to assumption by the University of all teaching responsibility for internes, medical clerks and students. This produced one of the finest clinical teaching facilities in Mid-America.

Antibiotic Era

Great changes have taken place in medical thought and action since 1917. One of the most powerful forces in modern history, antibiotics, was only a word in the unabridged dictionary. Many of the other medical tools and ideas which we now employ daily were unknown then. The now rapidly expanding fields of ecology,* cybernetics and others with their probable medical implications were also not known or understood.

And how some ideas and value judgments

Eczema of many years... controlled in two weeks

Before treatment

After treatment —
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side

effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive non-permeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyoderma will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

have changed! Random opening of the 1917 Volume of "The Journal Lancet" discloses an editorial (Page 120) which states in part:

Planned Parenthood

"A pamphlet entitled 'Family Limitations' by Margaret H. Sanger is the pamphlet that has caused so much discussion relative to birth control; . . . the newspapers have detailed the account of Mrs. Sanger's arrest, and her imprisonment for thirty days for circulation of the pamphlet, as well as for clinics that she conducted in New York and Brooklyn. The pamphlet is by far one of the plainest and broadest that has ever been circulated. . . . A few years ago a physician of Minneapolis wrote a book on sexual problems dealing with birth control. His book was confiscated, he was arrested, tried for dissemination of obscene literature, and *was sentenced to the penitentiary for one year*. Mrs. Sanger, however, gets off with thirty days, which is too short a sentence considering the advice that she gives women in her clinics and through her pamphlet."

The Golden Years

The gentlemen whom we honor in 1967 upon the completion of fifty years of medical service to the people of Minnesota have seen all of the preceding changes and many more. In addition to the eradication of countless infections by means of antibiotics, they have witnessed vast improvement in the management of diabetes and tuberculosis, the control of pernicious anemia, the virtual elimination of smallpox, rabies, diphtheria and poliomyelitis. They have seen spectacular achievements in the field of thoracic surgery, both pulmonary and cardiac, beginning with the removal of a lung by Evarts Graham in St. Louis, on through the expanding area of neurosurgery and up to the present work in organ transplantation. There is still much to learn about the cause and cure of cancer, aside from early diagnosis and treatment, and about heart and cerebrovascular disease, genetic problems, degenerative diseases of old age, and many others; but we can hope

that the sons and daughters of these fine men will help in accomplishing these monumental tasks.

Of the twelve physicians whom we honor this year, I have heard glowing reports, both personally and professionally. They are Einar Andreassen, John Stuhr, Fritz Pearson, Gustaf Nordin and Herbert Molander. Andy Sinamark is an old and valued friend; his work in the fields of ophthalmology and otolaryngology in Hibbing is known and appreciated throughout Minnesota. In addition, he has contributed valuable time and effort to a non-profit, voluntary organization, The Minnesota Society for the Prevention of Blindness. Ed Robb practiced pediatrics on a high level, with Drs. Rodda, Wilder and others for many years in Minneapolis. Art McFarland is a dear old friend who seems just as active and alert today as he was when he first joined Dr. Louis Nipert in practice years ago. He is the only medical man I know who was so conscientious, sympathetic and successful in his work that a wealthy patient made him a present of an expensive automobile; Tom Devereaux keeps rolling along in Wayzata; the years do not seem to affect him either. He and Dr. McFarland and I have been members of the Eitel Hospital staff for many years. John Lepak finished his teaching fellowship at the University Hospital a year or two before I began mine; his outstanding reputation in the field of internal medicine is well known. Charles Conner was a careful, able otolaryngologist whose office was adjacent to that of ophthalmologist Frank Burch. Ted Sweetser has been an outstanding urologist in Minneapolis for years. He and I enjoyed the dubious pleasure of being retired from the University faculty on the same day a few years ago.

It has been a rich experience to have had the friendship and the opportunity to emulate the qualities of these admirable men. We wish them all many more years of good health and fruitful endeavor.

Virgil J. Schwartz, M.D.
Minneapolis, Minnesota

Fame is something which must be won; honor is something which must not be lost.
—Schopenhauer

In peptic ulcer... antacid therapy with a new benefit

CONTAINS A BALANCED
COMBINATION
OF THE MOST WIDELY
USED ANTACIDS—
FOR RAPID
NEUTRALIZATION.
PLUS SIMETHICONE—
TO CONTROL
THE FACTOR WHICH
ANTACIDS ALONE
CANNOT INFLUENCE.

Mylanta[®]

- In Mylanta, aluminum and magnesium hydroxides are balanced to minimize the chance of constipation or laxation and still achieve rapid acid neutralization and pain relief.
- The positive action of simethicone helps relieve the painful gas symptoms which often accompany the peptic ulcer syndrome.
- The nonfatiguing flavor and smooth, nongritty consistency of tablets and liquid encourage continued patient cooperation during long-term therapy.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) of liquid contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. **Dosage:** one or two tablets, well chewed or allowed to dissolve in the mouth, or one or two teaspoonfuls of liquid to be taken between meals and at bedtime.

The Disturbed Patient

IF AN AMERICAN Board is established in the Art of Medicine, the practical examination will be given on the type of cases described by Babb and Steinhilber elsewhere in this issue.* For a physician mastery of the art of handling patients (the Art of Medicine) is a prerequisite to successful therapy. It is difficult for the physician in training, concentrating his entire attention upon anatomic and physiologic evidence of disease, to devote equal attention or even any attention to the emotional problems which may be of significant importance. The fundamental purpose of visiting the patient must be to prolong life and relieve symptoms. Sometimes this may be done by discovering an elusive physical finding leading to the diagnosis of an unusual disease, followed by medical or surgical cure, a very satisfying outcome to the patient and especially to the physician.

When a vast and expensive medical survey leads apparently to nothing, the physician may be as frustrated as the patient. Under such circumstances the physician may react ineptly, artlessly, in response to his own frustration, fixing a label of hysteria or neurosis on a patient because the studies de-

signed to discover the disease turn up all blanks.

The greatest rewards in medicine should be in the proper care of the neurotic, hysterical, and psychotic patients. There is no great art to the successful diagnosis and treatment of a straightforward medical problem in a patient able to give an accurate history, who accepts reasonable diagnostic procedures, and follows therapeutic instructions carefully. The real expression of the art of medicine is exemplified in the physician's care of the difficult patient who cannot give a logical history, who has symptoms in every system, and discourses at length upon the difficulties he has with each and every one of his organs. It is satisfying to pluck the plum of pathology from the foliage of noncontributory symptoms. It is less satisfying but equally important to handle the situation when no such pearl of disease appears. Should this prove to be an excessively frustrating experience to a young physician, he should consider avoiding general practice and internal medicine, where this situation is the rule rather than the exception. There is, however, great satisfaction for the physician skillful in the art of the care and feeding of the neurotic patient.

Reuben Berman, M.D.
Minneapolis, Minnesota

The object of any piece of writing is to make your reader understand exactly what you have to say — and understand it as quickly and effectively as possible. To make your reader do this you must lay out your article, report, story — whatever it may be — like a carefully surveyed road. Otherwise it will never get anywhere in particular; it will merely stop short after a certain number of pages. For lack of plan too many pieces of writing find themselves “miserably straggling to an end in sandy deltas.” We are all too busy to read that sort of thing.

David Lambuth
The Golden Book on Writing

Most medical fads are like some women's fashions — frail, fickle and costly.
— Noah Fabricant

She simply sits while the party goes on around her, already used to being the girl who is left out. She tries to lose weight—but her emotions won't let her. She becomes irritable and depressed when she doesn't eat, and anxious when she considers her future. So each time she gives up.

"What can I do?" she asks when she visits your office. "How can I ever stay on a diet and lose weight?"

A PARTICULAR COMBINATION OF ACTIONS

Ambar #2 Extentabs®

methamphetamine hydrochloride 15 mg., phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

FOR THE NEEDS OF THE DIETING WOMAN

A. H. Robins Co., Inc.
Richmond, Va. 23220

A-H-ROBINS

Ambar is formulated to specifically meet both the physical and emotional needs of the woman who is trying to lose weight. *Methamphetamine hydrochloride* has a powerful suppressant effect on the appetite and also provides a gentle psychic lift to improve mood and encourage activity. The *phenobarbital* component, through its classic calming action, helps control irritability and anxiety, and helps counteract excessive CNS stimulation.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY / Indications: Ambar suppresses appetite and helps offset emotional reactions to dieting. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. See package insert for further details.

Observations on the Diagnostic Capabilities of Laboratory Tests

A RECENT ARTICLE* in MINNESOTA MEDICINE describes an attempt to evaluate the diagnostic value of decreased serum cholesterol levels — an attempt of special interest in that it considers the influence of the presence of pathological states *other* than the one for which the test is requested. Thus it seems timely to consider some general questions concerning the informational value of laboratory tests in medical practice.

The clinician has come to rely heavily on the laboratory to assist in providing information on which to base a diagnosis. However, the diagnostic implications of test results are frequently not clear. Hence, an evaluation of the diagnostic capabilities of tests is essential.

Diagnosability

One of the most important considerations in determining the value of a test is the probability (or odds) that a person has the disease if the test result is "positive." For this probability we shall employ the term "diagnosability of the test."** Before exploring the concept of diagnosability, we must consider two other properties of tests. First, not all persons with a disease yield a positive test result. *Sensitivity* is defined as the probability that a person with the disease *will* have a positive test (i.e., the proportion of people with the disease who will yield a positive test). Thus, if the test under consideration has a sensitivity of 93%, a person with the disease has a 93% probability of yielding a positive test. In contrast, 7% of those with the disease will yield a negative test. These 7% are called *false negatives*.

Second, *specificity* of the test is defined as the probability that a person free of the disease will yield a *negative* test. Thus, if a test has a specificity of 96%, a person free of the disease has a 96% probability of yielding a negative test. However, 4% of those without the disease will yield a positive test.

These 4% are called *false positives*.

Now, again consider diagnosability and its formulation. Postulate, for example, a test with:

1. a sensitivity of 95% and
2. a specificity of 95%

(this test would generally be regarded as a good one indeed).

Consider further, as an example, a population of one million persons, 1000 of whom have the disease (a fact usually estimable from experience, e.g. from surveys). Thus, the *prevalence rate* of the disease is 1 per 1,000. The formulation begins with the following table:

TABLE 1

Total Population	Diseased	Not Diseased
1,000,000	1,000	999,000

Since the sensitivity of the test is 95%, 950 of the 1,000 diseased persons will demonstrate a positive test result and 50 a negative test:

TABLE 2

Total Diseased	Test Positive	Test Negative
1,000	950	50

Since the specificity of the test is 95%, then 95% of the 999,000 individuals who are not diseased will demonstrate a negative result and 5% a positive test:

TABLE 3

Total Not Diseased	Test Positive	Test Negative
999,000	49,950	949,050

The preceding two tables illustrate that the hypothetical population would have 50 false negatives and 49,950 false positives if all million individuals were tested. The three tables can be combined into a single table which leads to the additional information needed to arrive at diagnosability:

Table 1 appears as the lowest line of Table 4. Table 2 appears as the left hand

TABLE 4

Test Result	Diseased		Total
	Yes	No	
Positive	950	49,950	50,900
Negative	50	949,050	949,100
Total	1,000	999,000	1,000,000

column of figures of Table 4, and Table 3 appears as the middle column of figures of Table 4. The right-hand column of Table 4, Total Positive and Total Negative, is new information. Now the diagnosability is defined as the proportion of those with a positive test who turn out to have the disease. In this example the diagnosability would be equal to 950 (those with the disease and with a positive test) divided by 50,900 (those with a positive test with or without the presence of disease). If one pursues the arithmetic, he will find that the diagnosability of this hypothetical test *in this situation* is 0.019 or 1.9%! In other words, a person with a positive test has less than a 2% chance of having the disease, and this using a test with 95% sensitivity and 95% specificity (a good test)!

With a little algebra the following formula can be shown to hold where D = diagnosability, S_e = sensitivity, S_p = specificity, and P = prevalence rate of the disease:

$$D = \frac{(P) (S_e)}{(P) (S_e) + (1-P) (1-S_p)}$$

A few comments are in order concerning the characteristics of this formula (besides the fact that a good test can yield a disappointing diagnosability):

1. The diagnosability improves with higher sensitivity and/or specificity, everything else being equal. (The results in the example would have been even poorer with a sensitivity and/or specificity less than 95%).

2. The diagnosability would be 100% if the specificity were 100%, no matter what the other variables were. A similar relationship *does not* hold with respect to sensitivity.

3. *The diagnosability depends very strongly on the prevalence of the disease in*

the population. For example, with a test of 95% sensitivity and 95% specificity and with a prevalence rate of 50% (i.e., half of the population has the disease), the diagnosability would be 95%. Thus, *diagnosability is not a static, constant factor but varies according to the situation in which the test is applied.*

It is essential, at this point, to enumerate some of the assumptions in the use of the above formula:

1. We are dealing with a definable illness condition.

2. We have a test which can be categorized as positive or negative.

3. We know (from experience, possibly from a survey) the sensitivity and specificity of the test and the prevalence of the disease.

We frequently do not know the answers to some of these implied questions. We can sometimes get approximations, via other means, to the variables listed in 3. And we have to modify our conclusions as assumptions 1 and 2 are not met.

End-Point or Disease State

One of the important problems concerns the definition of the end-point or disease state. Are we dealing with a well-defined single pathologic condition, a group of illnesses, or a vague state of illness? What happens when a person also has another illness which may affect the test result one way or another? (This is the root of the problem considered by Dr. Hunter.) In the present example, the situation is such as might be encountered in mass screening where no information is available about the subject other than the test result. But when the clinician orders a test performed, he orders it because he has a suspicion based on other information he has about the patient. Thus, a person with a positive result to the test described in the example may have a greater than 2% chance of having the disease if he also has certain signs and symptoms. One satisfactory way around this problem might be to consider the *conditional* use of the formula. The sensitivity of the test might be higher for persons with more

MINNESOTA MEDICINE

severe illness who have signs and/or symptoms that cause them to seek medical attention. And, more important, the prevalence of the disease may well be higher among those who have certain signs and symptoms than among the general population. Whether or not other diseases will have an effect on test results would influence the sensitivity and specificity of the test for the disease under consideration. Hence we should perhaps employ the formula separately and derive separate estimates of diagnosability, *given different sets of other information about groups of subjects*. Such separate estimates are called *conditional* probabilities, in technical statistical jargon.

Philosophical Problems

There are many philosophical problems involved in diagnosis in general, as well as in interpretation of laboratory results. For instance, what is the definition of an illness? Is it based on microscopic pathologic status (e.g., astrocytoma of the brain) with the symptoms described only as associated with the illness? Is it based on physiologic aber-

rations (e.g., right heart failure)? Is the test result itself considered a diagnosis (e.g., hypocholesterolemia)? What is a "positive" test or what should it be? Is the test used singly or in combination with other tests? These and many other problems (e.g., laboratory errors and refinement of test mechanics) are important to the subject but are beyond the scope of this communication.

Thus, while the arguments presented above can not provide complete or definitive answers to the problems of test interpretation (nor could they in such a brief and general treatise), it is hoped that the reader may gain some additional insight into rational criteria for interpretation of test results. One thing is certain: while laboratory tests can be very helpful in diagnosis, they cannot supplant clinical judgment based on *all* of the relevant and available information. Nor will it ever, in our opinion, be possible to use any formula as a replacement for clinical acumen, but rather only as another tool in the physician's diagnostic armamentarium.

Radical Pancreatoduodenectomy: Diminishing Mortality Rate

THIS REVIEWER was taken to task several years ago by a purist in the profession for having spoken of tumors of the ampulla of Vater. It was pointed out that an ampulla is merely a dilatation or opening and that, properly speaking, we should always use the term papilla of Vater. This seemed a minor point to me, but I suppose we should all correct our habits.

The article of Dr. Yoshio Sako* presents quite lucidly the experience of one group of physicians with tumors which are most difficult to cure and frequently most difficult to recognize. Their experience has been quite similar to ours, especially in a progressively diminishing mortality rate after

radical pancreatoduodenectomy.

The current efforts directed toward preventing pancreatic fistula after this operation have been largely responsible for the improved rate. The use of an indwelling tube (usually made of a plastic material) within the main pancreatic duct, which is anchored securely and allowed to pass spontaneously later, has been most helpful in our hands. Accurate mucosa-to-mucosa suturing of the duct to the jejunum is theoretically ideal, but it does not provide for the pancreatic juice which might drain from the cut surface of the gland and from tiny ducts which cannot be recognized. For this reason we have continued to invaginate the entire cut end of the pancreas well within the jejunum.

*Sako, Yoshio: Carcinoma of the Pancreas and the Ampulla of Vater. *Minnesota Med* 50:169, 1967.

AGE.....

M.M.

The point is brought out that persistence in resection in too high a percentage of cases leads to poor results because malignancy must be left behind, malignant planes are invaded, and the results are worse than those after mere palliative surgery. Our experience has been that palliation is better after resection than after some lesser operation, because pain is much less of a factor and occlusion of palliative anastomoses may not be so common.

The head of the pancreas continues to be the most troublesome area for the surgeon,

because a tumor there may be much more extensive and invasive than the surgeon originally realized. Until something better is available, we must continue with radical pancreatoduodenectomy, even in cases of malignancy of the head of the pancreas, because we are seeing an increasing number of five-year survivals. At the same time we must be alert to all possible contraindications so that we will not be attempting the impossible.

An Obstetrician Proposes a Change in the Abortion Laws

The recent controversy over the proposed changes in the state abortion law have been directed primarily to the change recommended by the American Law Institute in 1959. Those in favor of such a change point to the three major areas where legalized therapeutic abortion is needed, namely, rape, incest, and for medical (organic or psychiatric) disease of either the mother or fetus. The opposition to this change is concerned with the eventual outcome after physicians are given broad license to interrupt pregnancy.

To the practicing physician the theoretical problem is neither moral nor medical. It is the repugnant fact that currently antiquated legal statutes dictate how a scientific judgment must be made. Although the theoretical punitive threat probably does not alter many decisions, the performance of justified abortions outside of the legal sanctions is contrary to intellectual honesty. The principle should be that medical decisions are based upon scientific facts which educated practitioners may agree upon. Thus, if a case arose one should have the legal right to debate the application of therapeutic abortion on scientific grounds alone.

Therefore, it would seem that some compromise law should be passed which would cover the three major areas in question (rape, incest, and medical disease), but which would also offer the protection of sound scientific judgment. The following proposals for incorporation would seem to fulfill this need.

First, in the area of *rape* the obvious problem is the establishment that rape actually occurred and not merely a "change of heart." The new knowledge of reproductive physiology can eliminate this grave decision from the physician's shoulders. We as physicians are now able to effectively prevent pregnancy up to 48 hours *after* intercourse. This has been demonstrated by Morris and Van Wegenen.¹ In the true rape case the victim would only have to present herself to a physician within 48 hours after the incident and receive the necessary medication. Naturally police, physicians, and the public would have to be educated to this new form of therapy. The fact remains that therapeutic abortion is *not* needed as a solution to this problem.

The second area of concern is that of *incest*. Again, the establishment of this social crime is difficult and could best be made by our legal colleagues. I would therefore suggest that the "crime" must be decided upon by a judicial hearing. If it is established to be an incestual pregnancy, the law should allow for therapeutic abortion if the concerned parties so desire. This would also provide for the prevention of a recurrence of this act since the judicial establishment of the incestuous act would automatically lead to prosecution of the actor.

Finally, the much broader area of *medical* indications is changing continually. It is not my purpose to debate specific medical indications such as nephritis, heart disease, depression, rubella or the ingestion of

drugs like thalidomide. I believe that when the dangers of a medical problem are established physicians can agree upon the correct action. If the medical effects are uncertain there will be disagreement. Few physicians would argue with the therapeutic axioms of insulin treatment for diabetic patients with acidosis or penicillin treatment for patients with beta hemolytic streptococcal pharyngitis. These areas seem clear. To provide the safeguards to ensure that scientific facts are determining the abortion recommendations, therefore, I would propose that the decision be made by a majority vote at a committee meeting. The committee should be composed of five physicians not including the aborter. Members of this committee should include one board-certified obstetrician, one internist, one pediatrician and one psychiatrist. If anyone objects to this form of committee decision on the basis that it is difficult to establish it in the small community, then I would suggest that the consideration of destroying a human life is the greatest decision that a physician will ever make and merits patient transfer to a center where this group of experts could be assembled. Whether or not a specific medical indication is valid will depend upon scientific judgement. This would also offer the patient expert medical consultation to be certain that other less well known forms of therapy were not being overlooked. Regardless of one's moral convictions, if a group of knowledgeable scientists recommended a form of therapy, this should be acceptable if one is not required to perform the act himself. Finally, the performance of therapeutic abortion should be a reportable operation under state law and this would then allow an analysis of data and a control over committee decisions.

The broad principles for a new abortion law have been presented. The pros and cons of the individual "trees" have not been debated but only the concept of the "forests." This then would represent a compromise which would legally allow for the performance of therapeutic abortions, but would also supply safeguards to guarantee that abortion would be performed only for sound scientific reasons. The technical wording of such a law has not been presented since it would seem more logical to have this done by those who are so trained. It is hoped that such wording would be guided by sound medical judgment.

The Editor's Soliloquy

Your Senior Peers

By public consensus I have finally become a 'senior citizen.' I deplore the term — not because of the chronological age it signifies but because of its sly innuendoes. As the word 'juvenile' implies callowness and lingering moisture behind the ears, 'senior citizen' (while sounding smugly dignified) is no more than a genteel substitute for 'oldster' — connoting peering eyes, cupped ears, unlatched jaws, a Parkinsonian hand, doddering locomotion, failing comprehension, and all the rest of the dreary reminders that mortal man's path leads but to the grave.

However, infirmity does not arbitrarily set in the very day a man becomes 65. It can be evident long before that date; it can delay until long after; happily it may never make its appearance.

Some Eastern societies revere their elderly members; some even worship their ancestors. In our culture, however, when we defer to our seniors, it is all too often in a veiled tone of patronage instead of with genuine respect.

If 'junior' would only list when his elders suggest: "Take thou our best and improve upon it: profit from your heritage — do not repudiate it," then our world would not have to be eternally gyrating in concentric circles through the same point but could spiral upward to even higher levels.

Disavowing all charges of wishful thinking, I prefer to regard the majority of my contemporaries as men seasoned by their years — with undiminished physical vigor and mental capacity attesting to the fact that age need not impair human faculties. I observe these gentlemen walking among us with cool detachment — no longer harried by ungovernable impulses, victimized by undue excesses, or driven by vaunting ambition.

It is with this elite group of so-called senior citizens that I now identify. To our younger colleagues we say: we have not become either pedants or fossils: in essence we are still your peers; but in addition we are the unique possessors of an *esprit-de-corps* acquired by surviving and transcending the hurly-burly of youth and middle age with its caterwauling over mere trifles and agonizing over transient problems that only waste man's precious time and substance.

Finally we say to our junior brotherhood: when you become members of our distinguished 65-and-over fraternity you too can join Robert Browning's Rabbi Ben Ezra in saying:

"Grow old along with me!

The best is yet to be,

The last of life, for which the first was made."

Carl O. Rice, M.D.

Some individuals resemble rare wines; they are in their prime when they are aged.

— C. O. R.

Old Doc Hess says: I can never see much sense in having that warning sign on the back of the car. By the time you see it the danger is over: student driver.

Board of Editors

MINNESOTA MEDICINE

HONOR AWARD

Minnesota Medicine Medical Writing Awards, 1967

It is the pleasure of the Board of Editors to announce the winners of the sixth annual Minnesota Medicine Medical Writing Awards chosen from articles published in MINNESOTA MEDICINE during the year of 1966.

The first place plaque is to be awarded to Doctors Richard L. Reece and Philip A. Olson of Minneapolis. Their article "Coumarin-Induced Bleeding Complications — Report of Eight Unusual Cases from One Hospital" appeared in the November issue of MINNESOTA MEDICINE, page 1677. The presentation will take place during the annual meeting of the Minnesota State Medical Association in Duluth at the New Members, County Officers and Delegates Dinner on Sunday, May 14.

Certificates for excellence in medical writing will be awarded to the author whose article was felt to be particularly outstanding by the Board of Editors.

AMA • 116th Annual Convention • Atlantic City, New Jersey • June 18-22, 1967

Come to Atlantic City—one of America's favorite by-the-sea playgrounds—and join your colleagues at the AMA's 116th ANNUAL CONVENTION!

Fine hotels and motels, excellent restaurants, plus all the advantages of a lively resort make this year's Convention a must for you and your family. Atlantic City provides a superb setting for a summer classroom and all the latest techniques of modern medicine. Plan to be one of the participants in this rewarding four day postgraduate education program.

• Four general scientific sessions • 23 section programs • 575 scientific and industrial exhibits. Lectures, panel discussions, motion pictures, and color television. Plan to attend—continue your postgraduate education.

RESERVE NOW for the SCIENTIFIC AWARDS DINNER in honor of the Scientific Award Winners—Wednesday, June 21, 1967. Since space is limited, we suggest you make your reservations before June 1, 1967. Tickets are \$10.00 each, payable in advance.

See JAMA May 8, 1967 for complete scientific program—forms for advance registration and hotel accommodations.

Fifty Years of Honorable Service in Minnesota

The presentation of certificates and pins to Minnesota physicians who have engaged in the practice of medicine for 50 years has become an impressive highlight of each Annual Meeting. According to custom the presentations are made during the course of the Annual Banquet. Few who have witnessed these ceremonies soon forget the setting of such an occasion at which these colleagues with a half century of medical practice to their credit so alertly respond to the roll call.

The custom of honoring Minnesota physicians who have served their patients and communities for a half century was established in 1942. Forty-one physicians were honored at the first ceremony. This group also included those who had passed the 50-year mark prior to 1942.

To be eligible for this award a doctor must have spent the majority of his 50 years practicing medicine in Minnesota.

In 1967 thirteen doctors were added to the membership rolls of the Fifty Year Club.

FIFTY YEARS

During the past 50 years filled with interesting and gratifying experiences, I have participated in two world wars, spent six years as a medical missionary in China, 14 years in private practice, and 12 years as the Area Medical Director in the Veterans Administration.

I remember the little Chinese boy with kala-azar, whose enlarged spleen filled two-thirds of his abdomen.

I recall the 300 Chinese wounded soldiers left in a freight train with no one to take care of them except four American boys, Dr. Paul Hodges and me.

I also remember handling other groups of wounded in another war, as the first casualties were returned from the Normandy beaches. Colored men of the sanitary companies handled them so smoothly and gently as they moved them from the L.S.T. boats to the waiting ambulances.

I remember the hospital train and the airfields overseas where the wounded soldiers had to be handled, and I think of the emotions experienced on V-E night in London when the lights were turned on for the first time after several years of blackout.

I remember driving a jeep to St. Lo on the day on which General Patton's army started a wide swing across the Brittany Peninsula. Twenty years later I returned to the United States cemetery at Omaha Beach. All of these incidents and many more come to mind as I think back over the events of the past 50 years.

Einar C. Andreassen, M.D.

I was born at Camelton, Indiana in 1888 and received an A.B. degree from the University of Indiana in 1910 and an A.M. degree in physiology in 1912. I graduated from Johns Hopkins University with an M.D. degree in 1914. Thereafter I served a rotating internship at Rhode Island General Hospital in Providence and a Fellowship in Otolaryngology at the University of Minnesota in 1917.

I served in the First World War in the American Expeditionary Force in France with Base Hospital 88 through the years 1917 to 1919, and did graduate work in otolaryngology at the Universities of Chicago, Pennsylvania, Harvard and Vienna.

I was associated with Frank E. Burch, M.D., St. Paul, in 1919, and I have practiced otolaryngology since then, in addition to being an attending physician at the Wilder Dispensary and the Miller Hospital.

I have been a member of the usual medical societies and began my retirement in 1956.

Charles E. Connor, M.D.

While reminiscing, I recall a beautiful day in June a few years back on the occasion of being a guest at an appreciation dinner given to me by my patients. Mail had been heavy for a few days — with best wishes directed to "Dear Old Doc," "The Old Pill-Pusher" and various other names that I cannot in propriety mention.

As I entered the banquet room I was completely overwhelmed by a group of doctors and their cheerful greeting as we were attended by numerous teenage girls, all of whom I had delivered. They had volunteered to serve as waitresses for a mass of friends and patients ranging in age from 14 to 90.

Warren, who always chided me that my medicine was no good, was there and advised me that he was coming to my office as often as he wished, whether I wanted him or not.

Pat, 85, who was caught by the police driving down the railroad tracks, was also there. He reminded me that I had given him permission to drive. Needless to say, the cops paid me a visit.

Reaching my 50th year in medicine has added a golden leaf to my garden of memories.

Thomas J. Devereaux, M.D.

FIFTY YEARS

A farm in Gnesen Township fourteen miles north of Duluth was my birth place in 1887. After attending St. John's University, Collegeville, and the University of Minnesota, I entered the Medical School and received my Doctor of Medicine degree in 1917.

1919 was the big year during which I opened up my office in the Lowry Medical Arts Building in St. Paul but continued as assistant Professor of Medicine giving clinics at the City and County Hospital in St. Paul. This hospital later became known as Ancker Hospital.

I have been pleased to serve as President of Ancker, St. Luke's and St. Joseph's Medical Staffs. Also many memories are with me from when I served as President of the Ramsey County Medical Society, St. Paul Society of Internal Medicine, Minnesota Society of Internal Medicine, Minnesota Academy of Medicine and Local Chairman of the American College of Physicians.

Cecilia Rosenthal and I were married in 1920, and we have three sons of whom we are very proud. One of our sons is Reverend Roy Conrad at St. Thomas College in St Paul.

John A. Lepak, M.D.

I was born in 1891 in the shadows of Longfellow School in Minneapolis and after attending the Columbia College of Physicians and Surgeons, I interned two years in the New York City Hospital. I was fortunate to be licensed in both New York and Minnesota and practiced with Dr. Harry Harlow Brooks in New York City for one year before entering the army in 1918.

Lillian E. Ferguson of Huntington, West Virginia became my wife that same year, and we have a son and daughter out of this partnership, living in Minneapolis. Besides my gardening and wild life studies, Lillian and I enjoy our six grandchildren.

Arthur H. McFarland, M.D.

Reaching the 50th year in the practice of medicine is an achievement for which I am exceedingly grateful. I give thanks to God, My Heavenly Father, and to Jesus Christ, My Lord and Savior, and the Holy Spirit, my constant companion, who made this a reality in my life.

The east side of St. Paul was my place of birth in March 1893. My graduation at 18 proved an epochal time in my life, for I was converted to a Christian faith in the living Christ who became my guide in the important years ahead.

I became a Junior Intern at Bethesda Hospital in St. Paul where I obtained acquaintance with men of ability and integrity who upheld the reputation of their profession, and after my graduation from the University of Minnesota in 1917 I received an appointment to serve as First Resident in Tuberculosis with Dr. Longstreet Taylor.

My name was entered on the roll of World War I veterans as a first lieutenant, though I was shortly discharged after the signing of the Armistice. I then accepted the position as City Physician for St. Paul, entered private practice, continuing in that capacity up to the present date.

It is my hope and prayer that, as God permits, I may show forth his praises and be ready always with meekness and fear to give an answer to all who may ask the reason of the hope within me. I am convinced after 50 years of medical practice that along with advice, drugs, surgery, diet and all forms of treatment, the greatest therapeutic measure at our disposal is prayer and I believe that it is of real importance that we recognize Christ as the Great Physician, one whose hands hold all power in Heaven and on earth.

Herbert A. Molander, M.D.

FIFTY YEARS

Gustaf T. Nordin, M.D.

Fritz R. Pearson, M.D.

Edwin F. Robb, M.D.

Andrew Sinamark, M.D.

When I graduated from the University of Minnesota Medical School in 1917 I made a resolution never to treat a patient unless I was satisfied that I knew what ailed him; if I didn't know, I was content to refer him to someone who did.

I was born in Almhult Smaeland, Sweden, in 1888, and emigrated to Minneapolis in 1905. I served my internship at the Swedish and Minneapolis General Hospital and thereafter received a commission as a First Lieutenant in the Medical Corps during the first World War.

I was married to Gertrude Jacobson in 1916, and during my absence in the War she served as a dietitian in the Deaconess Hospital until my return from France.

In 1919 I began practice in Minneapolis, but later studied radiology with Edward S. Blaine of Cook County and with Professor Forsell at the University of Stockholm during the fall of 1927, and also with Holzknecht in Vienna in 1928.

In January 1930 I discontinued my general practice to devote full time to radiology, and at the Swedish Hospital in Minneapolis I obtained the first 200,000 volt deep-therapy unit where I was the Director of the Department of Radiology.

After my retirement in 1956, my wife and I lived in California where I obtained a license to practice but never did so.

Dr. Pearson was born in Wisconsin, January 29, 1892, and graduated from the University of Minnesota in 1917. He has been very active in the Tuberculosis Clinic in the St. Paul Bureau of Health and has been responsible for the remission of this disease in this area.

I grew up in a small town in Missouri and lived next door to a young country physician who played catch with me, taught me how to throw curves and bat a ball. At that time I was 12 years old. I was making frequent trips into the country to "help" the doctor drive the team and set a broken arm. From this youthful experience the decision was made to become either a doctor or a big league ballplayer. The former won out.

After practicing pediatrics for 40 years in Minneapolis, I have now retired to Boca Raton, Florida, where life is most enjoyable but there are no kids next door with whom to play catch.

I am so grateful to the country doctor who influenced my life.

As a youngster I was proficient at fixing machinery on the farm; so I decided that I was cut out for an engineer. But in my second year at the University of Nebraska I flunked two subjects and then switched to a course in science, from which I graduated and then taught in a small college. However, I soon became convinced that I would never be a dedicated teacher.

I graduated from medicine at the beginning of the First World War and was immediately assigned to the Navy to do eye, ear, nose and throat work.

Later I endeavored to do general practice in my own home town but soon discovered that my friends and relatives remained with their own physicians.

Later the Veterans Bureau at Omaha offered me a position on the strength of my Navy experience, and within an hour I was on the job. During a leave of absence I studied in Vienna and found this to be one of the highlights of my life.

One day out of curiosity I stopped in at the Chiropractic College and was heartily welcomed as a prospect; but after spending a day visiting the classes and clinic, I knew sufficiently well that this type of healing was not for a medical man.

As I retire I look forward to reading books, an avocation I have deferred for many years.

FIFTY YEARS

I graduated from the University of Minnesota Medical School in 1917, served one year as an interne at the Anchor Hospital and was then in the United States Navy Medical Corps for another year. Subsequent to that I located in Stillwater in 1920, where I remember my first obstetrical patient as a transverse position.

I had no help except grandma holding the old-fashioned kerosene lamp. The husband was unable to tolerate the ordeal and took the lantern into the barn to do the chores while I proceeded with the delivery, chloroform container in one hand and a sterile glove in the other. Everything seemed to be progressing nicely until the lamp chimney tipped to the floor. Grandma then ran to the barn to obtain the lantern as we finally succeeded in delivering a healthy baby.

Early the next morning the mother was up preparing breakfast. "Early ambulation" in its infancy.

I have always asked God to help in difficult cases and I feel that the daily devotions that I have shared with my wife and church have helped me immeasurably in my work as a doctor.

John W. Stuhr, M.D.

Since you allow a considerable amount of leeway in the anecdotal-type of biography, I must say that the epochal incident in my life was the meeting and marriage of my staid New England Puritan Grandfather Sweetser to my Grandmother Kelley from Elphim, Ireland. Imbued with such genes, my father came west in the 80's and married another Irish girl named Higgins from Prince Edward Island, and in due time, just after World War I, I too married an Irish girl from Minnesota. We have lived happily together ever since. She can testify to the persistence of those New England characteristics which can be seen in both our children and our grandchildren. My son, Ted Jr., practices with me in Minneapolis.

If I were to follow the admonition of writing with the help of my wife, she might put some Irish glamour into the description of a professional anecdote.

Theodore H. Sweetser, M.D.

I graduated from the Manitoba Medical School in 1917, and during the last year of schooling we were registered as privates in the Canadian Army without pay; but upon graduation we received our majority. I was then promptly discharged because of iritis and subsequently served as locum tenens during the influenza epidemic of 1919.

From 1923 to 1925 I served a Fellowship at the University of Minnesota and thereafter practiced at the Newark Clinic until it was dissolved.

In 1947 I became the Medical Director of the Minnesota Mutual Life Insurance Company and finally retired in 1958 to Ely, Minnesota, where during the summer months I spend some time in the office of Dr. O. E. Sawyer while he takes a short vacation.

I expect to retire completely in May, 1967.

Alexander E. Venables, M.D.

FIGHTING CANCER WITH FILMS...

...is not news. What's news is that we've embarked on the most ambitious film program *for professional medical audiences* ever launched against a single disease. A half-million dollar film project is underway—with technical advice from the nation's leading medical authorities.

Five of these films are available now—

CANCER IN CHILDREN, DIAGNOSIS AND MANAGEMENT OF CANCER OF THE COLON AND RECTUM, ORAL CANCER, NURSING MANAGEMENT OF THE PATIENT WITH CANCER, and THE DENTIST AND CANCER. The balance will be released in 1967-1968.

As pioneers in the usage of medical films, we know their value as teaching tools. Our Units across the country know, too. Films are a vital part of their professional educational programs. We hope you will contact *your* local ACS Unit about this outstanding new series.

AMERICAN CANCER SOCIETY 

Curbstone Consultation

Ventricular Hypertension

QUESTION: I have heard that right ventricular hypertension may produce chest pain similar to angina pectoris from coronary atherosclerosis. By what mechanism is such pain produced?

ANSWER: The systolic pressure in the right ventricle is normally lower than the aortic diastolic pressure. For this reason right ventricular coronary flow continues throughout systole, whereas the left ventricular coronary flow ceases. When the right ventricular systolic pressure is elevated, ischemia can be anticipated associated with a reduced coronary flow.

Angina pectoris does not usually occur in cases of ventricular septal defects associated with pulmonary stenosis in which the right ventricular pressures are also elevated. Therefore, right ventricular hypertension cannot be the only factor involved. When the interventricular septum is intact the diastolic pressure in the hypertensive right ventricle may exceed the diastolic pressure in the left ventricle. With the existence of a large interventricular septal defect the pressures in the left and right ventricles remain equal throughout the cardiac cycle. These diastolic pressure relationships on cardiac collateral circulation may account for angina pectoris occurring only in patients with right ventricular hypertension that have an intact septum.

The best explanation for angina pectoris occurring in patients with right ventricular hypertension, therefore, seems to be on the basis of ischemia of the right ventricle secondary to reduced coronary flow resulting from elevated right ventricular pressure during both systole and diastole.

Tandearil® oxyphenbutazone

Tandearil in Painful Shoulder

Therapeutic Effects: Stiffness and pain may diminish within 2 days, and full mobility may be restored within a week. These effects are obtained with oxyphenbutazone alone or combined with physiotherapy or local hormonal injections. The drug is usually well tolerated and does not affect pituitary-adrenal function or immune response.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage. Make regular blood counts. Discontinue the drug and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Painful Shoulder: 600 mg. daily in divided doses for 2 to 3 days; 300 mg. daily thereafter. Usual duration of therapy: 2 to 7 days.

Availability: Tablets of 100 mg.

The Viewing Box

Man with Stiff Joint

A MAN, 56 years of age, was injured six months prior to his x-ray when his right leg was trapped between two hot metal billets, his clothes caught fire and he sustained third degree burns over both legs. Burns were most prominent about the right ankle, where exuberant granulations subsequently developed. Following debridement, two stages of skin grafting were successfully performed. This patient failed to regain normal ankle motion and ambulated with the aid of crutches.

At the time of these x-rays, examination revealed the grafted areas to be well healed with limited pliability suggesting moderate underlying fibrosis. Motion cannot be detected within the ankle joint, nor can inversion be performed. Dorsal flexion is limited to the talocalcaneal articulation, and motion is mildly restricted in remaining joints of the foot. There is no open drainage, and excellent pulsation is present in the dorsalis pedis artery with sensory testing normal peripherally.

What is your diagnosis? (See next page.)

A. P.

Lateral

Oblique

DIAGNOSIS: Bone and Joint Changes Following Burns

Serial x-rays in the severely burned patient may reveal changes in the bone and joint which can act as a deterrent to remobilization. These changes may be subtle or may show progression from normal bone to advanced skeletal involvement. All major joints may be involved, particularly, the elbow, knee and ankle. As defined by Evans and Blumel, skeletal alterations which cannot be ascribed exclusively to the initial thermal insult, fall logically into four groups.

Alterations Limited to Bone

Osteoporosis is common to all severely burned patients and may appear as localized or generalized bone atrophy. Localized change may be very limited but of great intensity and appear with an abrupt onset. In these instances it is felt that a vasomotor reflex phenomenon contributes to a local hyperemic state. Atrophy of the generalized type may be secondary to hyperemia, chronic inflammatory process and prolonged inactivity. However, malnutrition with protein insufficiency and/or electrolyte imbalance and adrenal cortical hyperactivity may also be etiological factors.

Periosteal new bone formation may underlie areas of severe burn or may appear in conjunction with a destructive process in an adjacent joint, due to acute hyperemia or a chronic inflammatory process. It is known to persist until there is good skin covering and does not continue to proliferate after the skin has been covered. Usually it is detected two to eight months after the burn.

Alterations Involving Pericapsular Structures

Pericapsular calcifications lie in the planes of ligaments or overlying tendons, have no attachment to bone, and may appear as spotty or continuous calcified plaques. They occur in both children and adults often as early as the second post-burn month. The precipitating causative factor is thought to be superimposed trauma with punctate hemorrhage in a localized area of tissue damage lying adjacent to the burn with mineral precipitation occurring in altered tissue pH. This type of spotty calcification may herald more serious joint impairment; however, it may not change and may disappear.

Osteophytes occur in adults and lie in the planes of ligaments at the site of bone attachment. Histological examination has shown that they represent simple new bone formation in fibrinous connective stroma, following superimposed minor trauma in the form of stress to a contracted and atrophic ligament.

Heterotopic para-articular ossification is found to lie deep in the plane of the surrounding muscle without evidence of actual replacement of muscle substance. This ossification has been observed at the hip, elbow and shoulder in both children and adults. It usually lies adjacent to, or under a burn and may be associated with immobility and progressive bone atrophy. Thus, as in the paraplegic patient, it may follow the degeneration of muscle, tendon or pericapsular soft tissue and hence is related to this chronic inflammatory state and the demineralization phenomena of continued release of bone salts. It is felt that the severely burned patient is constitutionally susceptible to minor trauma which may contribute to these pathological developments. Frequently this ossification occurs in the third month after the burn.

Alterations Involving the Joint Proper

Articular destruction and ankylosis are manifest early as capsular swelling, spotty pericapsular calcification and subchondral irregularity. As the destruction progresses, x-rays show soft tissue and intracapsular clouding, progressive destruction of the articulate surfaces, adjacent reactive periosteal new bone formation and ultimate bony ankylosis. Complete articular destruction may occur within a few weeks with resulting ankylosis within months. This is predominantly seen in children. The proximity of the joint to the burned area is not a constant factor in the genesis of intra-articular change. It has been postulated that this destruction may be due to bacterial invasion and this argument is supported by the knowledge that all severely burned patients have recurring transient bacteremia or septicemia of varying severity as long as there are open granulating areas. However, the clinical course is not typical of septic arthritis, and pathological examination has disclosed only panus formation and fibrinous adhesions without suppuration. Thus, it is more likely that the ankylosis is a degenerative process as it may occur in aseptic necrosis which may be initiated without bacterial invasion. It has been demonstrated that these changes may be minimized by early skin grafting and initiating active and passive exercises as soon as the condition of the patient permits. Should this not be feasible, less deformity will occur if the burned segments are placed in a functional position.

Alterations Secondary to Direct Involvement

Tangential sequestration or local bone necrosis will occur when a segment of bone is exposed by the burn, but any joint which is exposed will undergo septic destruction. Septic arthritis, articular destruction, and delayed ankylosis is the usual sequence.

The films reveal irregular pericapsular calcification in the peri-articular structures adjacent to the fibula and also the medial and posterior cortex of the distal tibia, mild varying periosteal thickening in the distal tibia and fibula, peripheral osteoporosis, subchondral destruction with clouding and early ankylosis within the ankle joint. A radiologist, when given a compatible history, will find these x-rays characteristic of that pathological change which may occur secondary to a burn.

Elbow grease is a standard prescription for success, but some men seem to get further using the soft soap.—Springfield Republican

Power does not corrupt men; fools, however, if they get into a position of power, corrupt power.—Shaw

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Tumor Conference

Thymic Cyst

TUMORS of the upper mediastinum, sometimes malignant and incurable, tend to defy identification of their origin. However, occasionally an upper retrosternal mass proves to be non-neoplastic and benign. The preoperative diagnosis, aided by appropriate radiographic techniques, can be made with some certainty and the organ of origin is readily identified under the microscope.

Case Report

A 26-year-old bricklayer saw his family physician, complaining of cough, sore throat and fever. Physical examination disclosed an upper respiratory infection in an otherwise robust young man. A chest film showed accentuation of the bronchovascular markings and a mass density in the right mediastinum. After his respiratory infection

Fig. 1 — P-A chest film showing a rounded mass density to the right of the ascending aorta.

Fig. 2 — On the lateral aortogram the anterior mediastinal mass, faintly outlined between arrows, does not fill with dye. (The streak across the sternum is an artifact).

Continued

had cleared the patient was referred to the thoracic surgery service, Minneapolis Veterans Administration Hospital, for further studies and treatment.

Physical examination and laboratory findings were normal. The medical history was negative except for two bouts of pneumonia during childhood. P-A and lateral chest films showed a rounded, 4 x 5 cm. anterior mediastinal mass, located to the right of the ascending aorta and intimately associated with it (Figure 1). On cinefluoroscopy the mass moved with the ascending aorta but did not pulsate expansively. An aortogram through the right femoral artery failed to show a communication between the aorta and the anterior mediastinal mass (Figure 2).

A right thoracotomy was performed. An encapsulated cystic mass, measuring 8 x 4 x 3 cm. was found between the superior vena cava, right atrium and ascending aorta. It was suspended on a 3.5 cm. long stalk which coursed into the area of the sternal notch. Cyst and stalk were completely excised. The patient recovered well and resumed work three months after the operation.

The histologic picture of the specimen was that of a thymic cyst. The stalk contained remnants of normal thymic tissue, composed of lymphatic and epithelial elements and Hassall's corpuscles (Figure 3). Much of the mass consisted of cysts filled with fluid and debris. The cyst walls contained many foreign body granulomas with giant cells and cholesterol clefts (Figure 4). Some cysts were lined with flattened and cuboidal cells in single and multiple rows. There was no evidence of malignant growth.

A mass in the anterior, superior mediastinum may originate in the thymus or in the thyroid gland, or it may be a teratoma ("the three T's"). Lymphoma, lipoma, fibroma, chondroma and angioma are less frequently found in this location. Rhabdomyosarcoma* of the anterior mediastinum is

*See Test Your Word Score Page 687.

Fig. 3 — Section of the stalk, showing lymphatic and epithelial elements of normal thymic tissue. The epithelial cells are predominantly seen in the central portion, together with a giant Hassall's corpuscle and an accompanying smaller corpuscle (magnified $\times 40$).

Fig. 4 — A section of the mass shows an epithelium lined cyst, a foreign body granuloma and cholesterol clefts in the left upper corner (magnified $\times 40$).

also rare. Some of these tumors show cystic degeneration or hemorrhage, especially when their rapid growth outstrips the blood supply. However, true cysts of pericardial or bronchial origin occur also in the anterior mediastinum. When the mass density lies in close contact with the aorta, as in the case of our patient, an aortic aneurysm must be excluded.

Some thymic cysts stem from embryonal rests which have migrated with the thymic anlage and are probably akin to dermoid cysts, originating in the thymus.¹ They are lined with flattened cuboidal or squamous epithelium. Other thymic cysts have no epithelial lining and are filled with debris, blood and cholesterol clefts. Castleman believes that they derive from degenerating Hassall's corpuscles.² A thymic cyst, in contrast to cystic thymoma, is by definition benign.

The microscopic picture of our specimen supports both theories of development. It shows: (1) cysts lined with flattened cuboidal cells, suggesting embryonal rests; (2) normal thymic tissue with a mixture of lymphatic and epithelial elements; and (3) Hassall's corpuscles of varying size, some of them degenerating with formation of cholesterol clefts and foreign body granulomas.

About one half of thymomas, solid or cystic, are associated with myasthenia gravis,³ and 15% of patients with myasthenia have a thymoma.⁴ This is not true for thymic cysts. A thymic cyst has lost almost all functioning thymic tissue. It is not neoplastic and represents incomplete removal of debris from the normal involution of the thymus.

Medical Men on Postage Stamps

Charles Laveran (1845-1922), French physician, pathologist, and parasitologist, Nobel Prize winner (1907), made valuable contributions to medical science in the fields of trypanosomiasis, leishmaniasis, and other protozoal diseases. His chief distinction lies in his continuation of the pioneer work of *Francois Maillot* (1807-1894) in the study of malaria and his eventual discovery of the parasite causing the disease. In 1954 Algeria issued postage stamps honoring both Laveran and Maillot.

Alvaro Alvim (1863-1928), Brazilian X-ray specialist and martyr of science, was honored for his work and sacrifice by a postage stamp issued in Brazil in 1963.

3 a.m.

**Sleep-interfering
anxiety and tension
can usually be relieved
with
EQUANIL[®]
(meprobamate) Wyeth**

Cautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. After prolonged high dosage, drug should be withdrawn gradually to avoid possibly severe withdrawal reactions including epileptiform seizures. Side effects include drowsiness and, rarely, allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Warn patients of possible reduced alcohol tolerance. Should drowsiness, ataxia, or visual disturbances occur, dose should be reduced. If symptoms persist, patients should not operate vehicles or dangerous machinery. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Other blood dyscrasias—aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia—have occurred rarely, almost always in the presence of known toxic agents. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. Prescribe very cautiously for patients with suicidal tendencies. Suicidal attempts should be treated with immediate gastric lavage and appropriate supportive therapy.

Contraindications: History of sensitivity to meprobamate.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Wyeth Laboratories
Philadelphia, Pa.

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by
absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert.

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylentetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Investment Opportunity

You have an investment in this boy. To protect this investment, you can join with other leading American businessmen in promoting the Treasury Department's Payroll Savings Plan for U. S. Savings Bonds. The Treasury's Plan works to build responsibility and diligence in citizens of all ages. It fosters the self-reliance and the concern for individual freedom, so necessary in the functioning of our democratic society.

Some day this self-reliance and freedom will take shape in the skills and knowledge needed for technological and industrial advances, for breakthroughs in science, for innovations along the production line

that will insure America's place in the world community and provide products for a competitive international market.

When you bring the Payroll Savings Plan into your plant—*when you encourage your employees to enroll*—you are lending a helping hand to every child striving to achieve his true potential. You are investing in the future power of America. In freedom itself.

Don't pass this investment opportunity by. Call your State Savings Bonds Director. Or write today to the Treasury Department, United States Savings Bonds Division, Washington, D. C., 20226.

in your plant...promote the **PAYROLL SAVINGS PLAN** for U.S. SAVINGS BONDS

Neurological Conference

Huntington's Chorea*

Dr. Robert Soll:**

Patients with Huntington's chorea† often realize eventually that they have a disease which will render them mentally and physically incompetent. Not only do they have the problem of their own body deteriorating, but they also have family problems and fears that their children may inherit this condition.

History

Doctor Thomas Rolewicz:‡

The patient is a 44-year-old woman who has a family history of Huntington's chorea. Her symptoms of the disease began about five years ago when she noticed that she tired easily and was irritable. After extensive testing a tentative diagnosis of early Huntington's was made. Since that time there has been a general progression of her symptoms. She comes to us now not specifically for treatment of her disease but for help in alleviating the problems that the disease has brought upon herself and her family. The 17-year-old son is described by his father and mother to be different in recent years; for example, in the past two or three years he has been having so-called "psychic blackouts." For this reason, we were able to have him also referred by their family doctor. He is a very interesting part of the total problem since he is old enough to realize what is happening. They have a nine-year-old son, too; however, he appears to be less aware of the situation.

The family history revealed that the mother of the patient died in an institution, questionably by suicide. The patient's maternal aunt and two uncles also died of the disease. Another uncle, age 57, has signs of the disease now. Among the patient's siblings are a 42-year-old sister and two brothers, ages 35 and 33 years. The 42-year-old sister definitely has the disease and the 35-year-old brother also has suggestive symptoms as well.

Physical Findings

On physical examination one's first impression of the patient when she walks in the door is that she is inebriated, an aspect that has caused her much difficulty as far as her social relationships are concerned. Her general physical examination is well within normal limits. Neurologically there are small twitching movements of her fingers and restless movements of her legs. While sitting, she very skillfully attempts to portray

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held every Wednesday from 1:00 to 3:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward Defoe in Pediatrics, and Dr. Robert Soll, in Adult Neurology. Held March 10, 1966.

**Neurologist, University of Minnesota Hospitals.

‡Student Doctor, University of Minnesota Hospitals.

Continued

these movements as natural in order to prevent other people from noticing them; for example, she would hold onto the chair with her fingers to prevent their twitching or use seemingly normal movements to cover up the abnormal ones. She also has very coarse tongue movements which she cannot control. An intention tremor is present in her upper extremities, making it very difficult for her to light cigarettes or perform many household tasks. Also her gait is moderately ataxic. The deep tendon reflexes are brisk bilaterally but plantar stimulation produces plantar flexion in both feet.

The patient is currently taking reserpine 4.0 mg. four times daily and seems to tolerate it very well.

Dr. Soll:

An interesting point is that she deliberately wears low-heeled shoes because she has a great tendency to fall. Although her sister has had trouble coughing, our patient has not been bothered in this way; but chewing her food has been quite difficult for her. In addition to the abnormal movements of her tongue, some facial grimacing is also present.

Psychological Evaluation

Dr. John Brantner:*

We made no evaluation of the patient's intellectual status. We assumed that this is correlated with her illness and that its course is pretty well known. We focused more on the personality constellations in the family by giving the entire family the Minnesota Multiphasic Personality Inventory. The patient herself was able to take the test but she was extremely slow. After three hours she had finished only half the items. We used a technique of somewhat questionable validity: after she had finished one half the test, we assumed the results would be the same as though she had responded to the entire test; we then scored what she had done by doubling it to obtain the final score. It does, however, fit her quite well clinically. She was defensive but showed a pattern of bitterness and some fundamentally religious aspects of her personality. She appears to be completely free from overt depression. Instead, she is hysteroid, denying what the illness is really going to be like. Psychologically I consider this to be a form of deterioration, a very serious maladjustment. She is, I think, denying the depressive qualities of her disease by insisting that it is going to make no change; furthermore, she is struggling against it unrealistically. She continues smoking contrary to medical advice; she insists on driving her car and considers her insurance company unreasonable because they won't renew her policy. It's unfortunate that her involvement takes this particular form since her husband shows up on his Minnesota Multiphasic Personality Inventory as simply a mildly depressed, unhappy, somewhat anxious person — rather passive in his orientation.

The older boy's Minnesota Multiphasic Personality Inventory is relatively within normal limits for a 17-year-old. He is a somewhat animated, passive, and feminine type. He does not appear so when you see him; rather he looks like a large, rather masculine, athletic type; but I believe it has been reported that he has not done much dating. The only thing I can suggest from the multiphasic is an identification with his mother: a warmth and closeness to her which has been badly damaged by her gradual deterioration. The younger nine-year-old boy was given a picture test equivalent to the Minnesota Multiphasic Personality In-

*Associate Professor, Clinical Psychology, University of Minnesota Hospitals.

ventory: the Missouri Children's Picture Series. The results were within normal limits. Evidently he has not been influenced too much, as his personality does not show any gross deviations from an average nine-year-old.

Social Service Evaluation

Mrs. Diane Crespin:*

The patient lives with her husband and her two children; however, she is not able to care for the children or the house. Her husband is an assistant manager in a large business. They live in a suburban community and have a \$14,000 mortgage on their house, on which they are paying \$170 a month. They owe \$1000 to their local drug store for medications. Another major problem is the fact that both parents have recognized that their older son is quite disturbed. Apparently he has lighted fires around the house from time to time. In school he may get 100 one week and the next week, a failure. I spoke with the school to find out about his performance and they reported that he had an I.Q. of 135 on the Stanford Binet test. Essentially, his problem seems to be that of achievement. Although he tests well above average, in the tenth and eleventh grade he had only an average record. Concomitant with his mother's downhill course this year, his grade average has also fallen to almost that of a D student, that is, two F's, a D, an A and a B. For the most part he has failed to hand in assignments; yet he is well liked by the teachers and makes a very favorable impression. The school personnel had believed until recently that the patient had a drinking problem.

Another aspect of the family situation is the tendency for them to harken back to the "golden ages" when they had foster children in their home, when things were better financially. However, this doesn't seem to be the case, because the state allows only \$70 a month per child. Their caring for foster children began in 1959, about the time when the patient's physical problems first began. Interestingly, this project was initiated by the husband. In my experience, women usually have applied for children; therefore, one visualizes this case as the husband's way of coping with his wife's inability to manage around the house. Foster-children care by this family was discontinued in 1963, although the patient states that it was only this year that it was discontinued. The reason this family was taken off the list of foster parents was that their neighbors, who weren't familiar with the patient's problem, called in, complaining that she appeared to be under the influence of drugs or alcohol.

Neurological Evaluation

Dr. Soll:

The patient has followed the typical pattern of involvement observed in most patients who develop Huntington's chorea. The usual age of onset is in the latter third decade or early fourth decade, although rarely a patient can begin to manifest symptoms in the teens or as late as the sixties. Symptoms of irritability first appeared in this patient between age 39 and 40. An emotional alteration is encountered frequently as the initial change and eventual mental deterioration almost always occurs,

*Social Service Department, University of Minnesota Hospitals.

Continued

However, neurological signs such as muscle twitchings and choreiform movements may lag behind the psychic changes for months or years.

During her evaluation in neurology clinic, early dementia was readily apparent; for example, she was unable to subtract 7 from 100 and had an extremely short memory span. Also there was a notable tendency for her to ramble, as may be shown here today. Hyperactive reflexes have been reported to occur during the course of this disease. We would not consider this patient's reflexes to be anything more than brisk unless some associated evidence such as ankle clonus or a positive toe sign were also present. Her mild dysarthria is at least in part the result of abnormal movements of her tongue.

Pathologically, the areas of involvement in the brain that produce these changes are quite diffuse. In addition to the severe degeneration and secondary gliosis of the cerebral cortex, marked changes also occur in the basal ganglia, particularly the caudate nucleus and putamen. Genetically this disease is inherited as a Mendelian dominant; therefore, 50% of the offspring are likely to have the disease. Thus there is a real possibility that both of their children may not have the disease at all. On the other hand, either or both of them could have it.

Patient enters the room.

Discussion

Dr. Soll:

When did you first notice a change in your health?

Patient:

About three years ago. I was having trouble chewing and I couldn't eat. I was losing so much weight that I was down to 88 pounds. Every time our foster children came down with anything like a virus, I'd get it too. I finally figured it was Huntington's chorea. I was already decided to accept it.

Dr. Soll:

How did you decide to accept it?

Patient:

Well, I talked to our pastor and he said, "If in case you have to trust the doctors, that's what they go to school for." You see, at first I thought I needed a hysterectomy because my mother had a hysterectomy. She didn't need it because she had ulcers and she didn't need it. Of course, she was a little nervous.

Dr. Soll:

Is there anybody else in your family that is nervous?

Patient:

Yes, my sister has Huntington's chorea.

Dr. Soll:

When did you know she had it?

Patient:

She has had it a year.

HUNTINGTON'S CHOREA

Dr. Soll:

How is she now?

Patient:

Not very good. She has had all kinds of side effects. She is on the same pill I am taking.

Dr. Soll:

Does the reserpine seem to help you a lot?

Patient:

Yes sir, and even better is this pill that my doctor gave me this past Christmas. Anyway it has some appetite control. Everytime someone said something to me. I have two boys, and the one boy is a teenager. But anyway, everytime anybody said anything I'd be sitting at the table and they'd say, "Mother, what on earth is wrong with you?" and I'd sit there and try to tell them and I couldn't tell them — but every little thing that they said — you know, so that's why when I started losing so much weight, I took this before meals, and everytime I call up the doctor.

Dr. Soll:

From where was your family originally?

Patient:

England.

Dr. Soll:

Does anybody feel that you have been drinking?

Patient:

Yes, quite a few times. Last October when I was getting off the bus, the bus driver looked at me and said, "Are you sure that you aren't drunk?" and I said, "No, I am not drunk." I said, "I have Huntington's chorea," and he said, "Yeah, I bet you do." So anyway —

Patient Leaves the Room.

The Patient's Husband Enters the Room.

Dr. Soll:

When did you first find out that your wife had her illness?

Patient's husband:

I first recall in November, 1961, she was in the hospital and some changes came over her. She showed some symptoms or some reactions that weren't quite normal. This went on through the winter, but we still weren't exactly sure of what it was. In March, 1962, it was confirmed that she had Huntington's chorea. That's when it was first noticed that her tongue quivered and she still couldn't walk around normal.

Continued

Dr. Soll:

Was she aware of her mother's illness and that she might have similar troubles?

Patient's husband:

Yes . . . When her mother died in March, 1952, we were all put on the alert by my father-in-law. He told us that it affects the genes and that any one of the children could have it; consequently, he suggested that they all have frequent check ups.

Dr. Soll:

How has your wife's illness influenced your outlook on life?

Patient's husband:

Well, she has had a morbid outlook in general, but this is not exactly true — I mean at times it was kind of exasperating. Yet, I know that things could always be worse.

Dr. Soll:

How do you envision the future?

Patient's husband:

Well, for myself, I am on the downhill side in age now so it won't affect me a great deal. The children are my greatest concern now. I went through a similar case with my own mother; she died of cancer the same year that I graduated from high school. You kind of look at the parallel situation. I suppose it is something you should not do, but one does anyway.

Dr. Soll:

What would be the most help to you in easing these problems that you have?

Patient's husband:

She actually has such an erratic schedule — she stays up at nights, sleeps by the day, etc. I started to say that actually when she is awake, the thing that bothers me is that I don't like to leave her alone. One thing is her smoking and I am afraid of fires.

Dr. Soll:

Have you thought of commitment?

Patient's husband:

Well, I know it is coming and her symptoms have increased rapidly in the past six months. It can't be any other way.

Dr. Soll:

Do your children realize the significance of her illness?

Patient's husband:

Our older boy is pretty well aware of it, but our younger boy only

knows that his mother is ill and that she will get worse rather than better. Actually some of her reactions are like a child. I think our younger son senses this also when he has to treat his mother as an equal which she should not be.

Dr. Soll:

Do you think it has influenced the oldest boy's work in school?

Patient's husband:

I think it has some. He is one that doesn't talk a great deal.

Dr. Soll:

Has he had any counseling in his school work?

Patient's husband:

No. I don't think the school knew about his mother being ill until recently.

Dr. Richard Magraw:*

You indicated that you were sort of writing yourself off in this as being on the downgrade of life, and I got the impression that what you are attempting to do is arrange things the best way for the boys.

Patient's husband:

Well, yes, I figured that they have a future ahead of them and I want to make sure that they can get the better things out of life right from the start that they should have.

Patient's Husband Leaves the Room.

Dr. Soll:

Dr. Lowry, what problems have you had with the patient?

Dr. Janet Lowry:**

She has been treated by us since 1960. Her chief complaints have been bronchitis, nausea and vomiting. As far as her neurological status is concerned, I don't think it has changed much. Occasionally she has expressed what appeared to be paranoid ideas; for example, one time she felt that someone was poisoning her food. The situation must be very difficult at home because she obviously is so borderline that the family has trouble. They treat her as though she were still normal and they have trouble recognizing that she is different. I think it is understandable that her husband might become frustrated. I don't believe that she is able to do very much around the house. The family does all the grocery shopping, cooking, and cleaning.

Dr. Magraw:

What was the immediate reason for referring her here at this time?

*Director, Comprehensive Clinic, University of Minnesota Hospitals.

**Referring physician.

Continued

Dr. Lowry:

The drugstore wouldn't give her drugs because the family did not pay their bill.

Dr. Soll:

Has the husband ever approached you with the problem of what may happen in the future?

Dr. Lowry:

No. We think she should be committed, but he hasn't accepted this.

Dr. Frank Meelhuysen:*

Is there any pathological information regarding the mother who died?

Dr. Rolewicz:

I am in the process of getting this. Her father had been extremely depressed after learning that this was a hereditary disease, and according to the patient, he has gone to great lengths to get a family history. He wants to help if possible, so he is going to be sending me this information also.

Dr. Robert Howard:**

Are there any techniques now available that can tell us whether the youngsters will develop Huntington's chorea or is it just a matter of waiting for it to develop?

Dr. Rolewicz:

The fact that the older son has so-called blackouts and is doing poorly in school might be an early manifestation of the disease and not just a reaction to the psychological impact of the situation according to the pediatric consultant. This has not been proven absolutely, but it does not seem to be a purely psychological reaction in some cases.

Dr. Brantner:

Pearson's¹ work with families with a history of Huntington's chorea showed that about half the male children developed psychic disturbances in late adolescence and approximately half of those who developed psychic disturbances were reacting to the revelation of the risks they faced. In the others, of course, it was the precursor of the disease itself.

Dr. Soll:

Patterson et al.² suggested in 1948 the possibility of using electroencephalography as a means of predicting the future development of Huntington's chorea in offspring of afflicted parents. Interestingly, 19 out of 25 subjects, most of whom were in their teens, had electroencephalographic abnormalities. Whether such a test actually would have predictive value still remains uncertain since I do not believe a follow-up report has been published on these specific cases.

*Assistant Professor, Department of Physical Medicine and Rehabilitation, University of Minnesota Hospital.

**Dean, College of Medical Sciences, University of Minnesota.

Dr. Howard:

Are there any unusual chromosomes that can be recognized by modern techniques?

Dr. Soll:

I am not aware of any study concerning gross chromosomal changes in Huntington's chorea.

Voice:

Is there a sex difference in the inherited pattern?

Dr. Soll:

No really significant difference. One recent report in 1961 by Oltman and Friedman³ gave a slight predominance to women, however.

Dr. Meelhuysen:

Is there any geographic dominance?

Dr. Soll:

Probably not. The original report of Huntington's disease was published in 1872.⁴ Huntington had followed his grandfather, who was also a doctor, on his rounds through a town in New England. They had seen several patients whose ancestors had originally come from England. At the present time the disease is not localized or limited to families in that area, since it has occurred sporadically throughout the world and in many races. In fact, in some it has occurred without any hereditary background. Usually a history of previous family involvement of the disease is found, however.

The Management

Dr. Soll:

It is pretty apparent that this is an extremely difficult situation. There is very little hope for improving the patient's physical condition. At the present time reserpine is one of the few drugs known to offer some relief for the abnormal movements in Huntington's chorea, but this has been strictly palliative rather than curative.

In this instance our attention can be better directed toward the husband and the children in an attempt to give them support and counsel.

Dr. Rolewicz:

I requested a consultation from Dr. Lee Schacht who is a counselor in genetics in Public Health and has worked with problems similar to those faced by this family. In general, he counseled the father as to what to expect. Much of this information is contained in a little booklet on Huntington's chorea. He suggested that the father wait a while before talking to the younger son, but felt that after we made this evaluation we could talk to the older son. He is looking forward to being able to talk to both boys when we deem it necessary.

Dr. Brantner:

There is one problem which I think is capable of solution. It is quite

Continued

evident that everyone is going to accept the patient's continued deterioration until someone can take over. At the present time, however, she is determined to postpone this as long as possible for herself, and she will postpone it indefinitely if she can. I am certain that the family can be manipulated in some way so as not to oppose these goals. The family is denying wanting to get rid of her but is somehow also weakening her determination to keep going. I think these feelings could be channeled so that the entire family could be working together to diminish guilt and conflict in the future.

Dr. Soll:

How do you suggest that this be done?

Dr. Brantner:

By frank openness with the three intact members of the family.

Dr. Magraw:

First, I'd try to meet the husband's needs. This man appears to be either largely denying his problems or living in hope of her commitment. I would try to find out what this really means in his life.

Dr. Lowry:

I think the boy is finally facing reality; for example, he would say to her, "I don't want to hear anymore about your Huntington's chorea." In a way, I think they approached me to encourage the patient to leave the family.

Dr. Magraw:

Isn't there some other option — maybe some kind of domiciliary living such as a nursing home? I don't know how realistic a plan this would be but another possibility would be assistance from a visiting nurse.

Robert Soll, M.D.
University of Minnesota Hospitals

Participating in the conference were: Dr. Robert Soll, Neurologist; Mrs. Diane Crespín, Social Service Department; Dr. Richard Magraw, Director, Comprehensive Clinic Program; Student Doctor Thomas Rolewicz; Dr. Frank Meelhuysen; Assistant Professor, Department of Physical Medicine and Rehabilitation; Dr. Janet Lowry, Referring Physician; Dr. Robert B. Howard, Dean, College of Medical Science; and Dr. John Brantner, Associate Professor, Clinical Psychology.

Nettle

The nettle is a good medicine for them that cannot breathe unless they hold their heads upright, and being eaten boiled with periwinkles it makes the body soluble. — Gerard

A large, dark, high-contrast microscopic image showing numerous spermatozoa. The sperm heads are bright and oval-shaped, with long, thin tails extending outwards. They are scattered across the frame, some appearing to be in motion. In the upper left corner, there is a smaller, square inset image showing a different view of the same or similar material, possibly a higher magnification or a different sample.

New view of an oral contraceptive at work

Although suppression of ovulation remains the primary mode of action of oral contraceptives, newer knowledge indicates that products like Norinyl-1 — which provide the combined action of both low-dosage progestogen and estrogen for the full treatment cycle — offer multiple contraceptive action that helps explain their unexcelled record of effectiveness. This report explores the secondary protective mechanisms against unwanted pregnancy offered by combined hormonal administration and the importance of the progestational agent in making such multiple contraceptive action possible.

Accumulating evidence has indicated that sparse, highly viscous cervical mucus has an adverse effect on the motility and survival of spermatozoa.

The estrogen-opposing progestational ingredient of Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.) reverses the usual mid-cycle picture of a thin, watery cervical mucus. The result — a built-in barrier that inhibits sperm from reaching the ovum should one be released. The inset in the adjoining photograph shows immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How the estrogen-opposing action of Norinyl-1 creates a hostile cervical mucus

Normally estrogen activity during the fertile midcycle stimulates the production of cervical mucus. The mucus at this time is profuse and watery—allowing maximum sperm motility and promoting penetration.

But what happens when Norinyl-1 is administered? Its potent progestogen, norethindrone, opposes estrogen stimulation of cervical mucus. Consequently, the amount of mucus decreases and its viscosity increases. This results in a sparse but thick mucus barrier that diminishes the vitality of the sperm and impairs its powers of penetration.

How hostile cervical mucus supports contraceptive action

The importance of these observations to the effectiveness of Norinyl-1 has been noted in a report on 89 patients taking this medication.* In all instances, cervical mucus obtained from cycle day 5 to cycle day 29 appeared scant and thick and exhibited little or no Spinnbarkeit. In the opinion of this investigator, the effect on cervical mucus may be sufficient to prevent conception. *Symposium on Low-Dosage Oral Contraception, Palo Alto, Calif., July 15, 1965.

Normal cervical mucus at midcycle in untreated patient permits sperm motility... promotes sperm penetration.

Cervical mucus is thin and watery with a stretchability (Spinnbarkeit) of 15 to 20 cm.

Thin, watery mucus crystallizes into this well-defined, fernlike pattern within a minute.

Spermatozoa appear healthy, are active and freemoving.

Hostile cervical mucus at midcycle produced by Norinyl-1 impairs sperm vitality... inhibits penetration.

Cervical mucus is scanty, thick and viscous. Spinnbarkeit is 1 cm. or less.

In thick, hostile cervical mucus the fern pattern is poorly defined or absent.

Immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

An endometrium unreceptive to nidation—another supporting contraceptive action of Norinyl-1

Let us suppose that an ovum is released—as occurs in an occasional, rare case—and somehow a sperm succeeds in penetrating the cervical mucus barrier? Should this come about, one additional action of Norinyl-1 may protect the patient from unwanted pregnancy—progesterone intake makes endometrial tissue unreceptive to implantation.

Endometrium of untreated patient

Normally the endometrium progresses through a proliferative phase stimulated by estrogen and a secretory phase stimulated by progesterone. During the secretory phase the endometrium is receptive to the fertilized ovum.

Unreceptive endometrium produced by Norinyl-1

When Norinyl-1 is administered its progesterone component—norethindrone—accelerates the secretory phase, suppressing glandular development. From day 11 on, secretory action is no longer present. The result is that during the latter half of the cycle the endometrium becomes unreceptive to egg implantation.

new

norethindrone/mestranol
combination

lower cost

new Norinyl-1[®] (norethindrone 1mg. $\bar{c}$ mestranol 0.05mg.) tablets

Reduction of oral contraceptive dosage to lowest effective levels has become a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now available in a new strength in which both norethindrone and mestranol are reduced 50 percent. Studies show that Norinyl-1 achieves fertility control with only 1.05 mg. of combined progestogen and estrogen per tablet.

Norethindrone was first reported for use as a progestational agent in human beings in 1955. Norethindrone 2 mg. with mestranol 0.1 mg., as an oral contraceptive, is currently in use by over 2,000,000 women. Clinical experience now establishes that Norinyl-1 also amply meets the criteria of reliability and safety.*

*Symposium on Low-Dosage Oral Contraception, Palo Alto, Calif., July 15, 1965.

PRESCRIBING INFORMATION

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia, or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of Norinyl-1 in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with Norinyl-1. Therefore, if such tests are abnormal in a patient taking Norinyl-1, it is recommended that they be repeated after the drug has been withdrawn for 2 months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibroids may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac, or renal dysfunction, require careful observation. 5. Although a cause and effect relationship has not been established, Norinyl-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, as in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are

indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged Norinyl-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Norinyl-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. A cause and effect relationship has not been demonstrated. 11. Because of the effects of estrogens on epiphyseal closure, Norinyl-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask the onset of the climacteric. 13. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

Side Effects: The following adverse reactions have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma, breast changes (tenderness, enlargement and secretion), loss of scalp hair, change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, erythema multiforme, erythema nodosum, hemorrhagic eruption, migraine, rash (allergic), itching, rise in blood pressure in susceptible individuals, mental depression.

The following occurrences have been observed in users of oral contraceptives. A cause and effect relationship has not been established: thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory results may be

altered by the use of oral contraceptives: increased bromsulphalein retention and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and but not extractable protein-bound iodine and decrease in T^3 values), metapyrone test, pregnanediol determination.

Other side effects reported to have occurred in association with use of this drug are dizziness, hirsutism, pains in legs, back, chest and abdomen, dysuria, drowsiness, vaginal discharge, libido increased and decreased, eruptions, hypermenorrhea, hypomenorrhea, increased appetite, G.U. infections, varicose veins, abdominal fullness, acne, headache, nervousness, allergies, blurred vision, pain in eyes, and itching in eyes. For complete clinical data, see package insert.

Dosage and Administration: 1. One tablet Norinyl-1 is administered orally for 20 days beginning on day 5 of the menstrual cycle (Count day 1 of the cycle as the first day of menstrual bleeding.) Repeat this dosage schedule for each cycle. 2. If no menstrual period occurs after a cycle of treatment (20 tablets) which patient adhered to the schedule, the patient must be instructed to resume taking the Norinyl-1 tablets 7 days after the previous day course was completed. For example, if the last pill of a previous cycle had been taken on Sunday, then a new cycle of treatment should begin on the following Sunday. 3. In the parturient woman, it is recommended that the first cycle of treatment should begin on day 1 of the first menstrual cycle. However, Norinyl-1 should not be administered during lactation.

Availability: Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.)—Dispensers of 20 and 60 and bottles of 250 tablets.

INFLAMMATION: A cellular fight for life

A SYNTEX REPORT based on recently developed hypotheses about topical corticosteroids, including the cellular theories of inflammation by Thomas F. Dougherty, Ph.D., University of Utah.

You are looking at a fibroblast fighting for life. This cell—one of the most common found in connective tissue—has literally been poisoned by cytotoxins released from other cells that have ruptured. Soon, if the abnormal activity of this fibroblast does not cease, it, too, will rupture and die—one more casualty in the inflammatory wave of destruction precipitated by injury.

Until a short time ago no one had ever witnessed such a scene at the cellular level. Now, through advanced cinemicrographic techniques, it is possible to view and photograph the inflammatory process as produced experimentally in living animal tissue. This method permits new insight into the mechanism of inflammation and the role of corticosteroids in therapeutic management. Equally important, these techniques shed new light on factors that may make one corticosteroid more effective than another—factors that can be correlated with other chemical, biologic, and clinical parameters.

Visual evidence of how corticosteroids influence the inflammatory reaction

Working with phase-contrast cinematography on living animal tissue, Doctors Thomas F. Dougherty and David Berliner of the University of Utah College of Medicine have actually filmed cellular events that occur during the inflammatory reaction. This remarkable study* and additional work by these investigators, as well as by others, have established a new theoretical biologic basis for the antiinflammatory effect of the corticosteroids. (It must be noted that other theories, such as the lysosome or so-called "suicide bag" theory, have been postulated, although it is quite likely that there are more similarities than differences among the various theoretical models.)

The inflammatory wave of destruction

In this investigation an injurious injection of gelatin is used to set off an inflammatory reaction in living mouse tissue. What follows is a wave of destructive cellular activity that comprises the inflammatory response to injury. Mast cells (which contain heparin, serotonin and histamine) take up water, swell and rupture, releasing their contents, which are toxic outside the mast cell wall. These toxins, in turn, cause disintegration of other cells (such as fibroblasts) and the release of additional toxic material. Capillaries, too, take up water and leak unformed blood elements, causing edema. And polymorphonuclears, lymphocytes and perithelial cells invade the inflamed site. As a result of all these changes, the cellular environment reaches a state of turmoil.

Phase-contrast microscopy showing mast cell before injury.

Mast cell (after injury) has broken up and released cytotoxins.

How corticosteroids change the picture

Corticosteroids appear to virtually stop the abnormal cellular activity that constitutes the inflammatory reaction. This permits the body's natural resources to clear up the inflamed area and repair the damaged tissue. This interpretation is supported by the fact that when the injurious gelatin solution is injected simultaneously with a corticosteroid — Synalar (fluocinolone acetonide) — the inflammatory pattern simply does not develop.

Fibroblast in high state of activity, much distorted.

Mast cells showing effects of corticosteroid action: cells are normal in size, shape and activity.

In summarizing his study Doctor Dougherty states: "...we also feel this work may explain why one corticosteroid helps a patient more rapidly and effectively than another. If it does, it is because one corticosteroid is the fastest, most effective inhibitor of the series of inflammatory events at the tissue level."

*A New View of Corticosteroid Action in Inflammatory Dermatoses, a film based on this study, is now available from your Syntex representative.

How advances in chemical design have achieved greater steroid potency

The chemical modification of corticosteroid molecules from the advent of hydrocortisone to the development of Synalar (fluocinolone acetonide) is a prime example of how biochemists can "design" to increase therapeutic activity and minimize undesirable side actions. Below, for example, we see the important changes that were made in reference to the hydrocortisone molecule to produce fluocinolone acetonide, one of the most active of all topical corticosteroids. As a result, a 0.01% preparation of Synalar (fluocinolone acetonide) has been reported to do the work of a 1% hydrocortisone product containing 100 times more corticosteroid. And it can often do it more effectively.

Hydrocortisone

Fluocinolone Acetonide (Synalar)

- a double bond between carbons 1 and 2
- fluorine substitutions at both the 6- α and the 9- α positions
- the addition of the acetonide at the 16- α , 17- α positions, thus providing one of the most potent topical corticosteroids available.

How bioassay tests are used to "predict" therapeutic potential

Biologic assays are another tool used by researchers to help establish the relative activity of corticosteroids. To date no single method of assaying corticosteroid activity has emerged as the ideal "yardstick" for predicting therapeutic potential. Taken together, however, these methods have proved useful. When such tests are run on various corticosteroids, a definite order of corticosteroid activity becomes evident. Compounds with the highest order of activity may be expected to merit clinical trial to establish their high therapeutic potential. When assayed by these methods, fluocinolone acetonide (Synalar) emerges as one of the most active topical corticosteroids, milligram for milligram, available for clinical application today.

THE THYMUS INVOLUTION ASSAY¹⁻⁴ is run on adrenalectomized rats. The sizes of the glands are measured, and the degree of involution caused by the steroid is determined as an indication of its potency. In the above photo, the comparative involution of thymus glands achieved with hydrocortisone and Synalar (fluocinolone acetonide) is shown. Untreated controls (A) show normal size. Group B—injected with 1, 2 and 4 mg. of hydrocortisone—show progressively smaller thymuses as does Group C—but with only 1/500th the dose of hydrocortisone.

THE ANTIGRANULOMA ASSAY¹⁻⁴ also utilizes adrenalectomized rats. Granulomas are induced by subcutaneous implantation of cotton pellets on either side of the thorax. The degree of granuloma inhibition achieved by a steroid reflects its potency. The above photo shows the inhibition of granuloma formation achieved with hydrocortisone and Synalar (fluocinolone acetonide). Untreated controls (A) show large, red granulomas adhering to the pellets. Group B, receiving hydrocortisone and Group C, receiving fluocinolone acetonide, show little, if any, granuloma formation. Fluocinolone acetonide produced the same effect as hydrocortisone with only 1/500th the dose. This assay, as well as the thymus involution assay, measures systemic rather than topical corticosteroid activity. Nevertheless, results by these methods correlate well with other assays and with the milligram potencies of topical steroids in current clinical use.

Worldwide clinical experience confirms the predictable therapeutic potential of Synalar

It is particularly gratifying that the promise of the advanced chemical design and high order of bioassay activity of Synalar (fluocinolone acetone) has been confirmed by widespread therapeutic application. Indeed, the impressive clinical response rate of Synalar has been documented in no fewer than 232 papers from 22 countries.

PRESCRIBING INFORMATION

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; *for emollient effect:* Ointment 0.025%, 15 Gm. tubes; *for maintenance therapy:* Cream 0.01%, 15 and 45 Gm. tubes, 120 Gm. jars; *for intertriginous or hairy sites:* Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; *for infected inflammatory dermatoses:* Neo-Synalar® Cream (0.025% fluocinolone acetone, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

CONTRAINDICATIONS: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. **PRECAUTIONS:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for pro-

longed periods of time. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. When severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. **SIDE EFFECTS:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. The neomycin in Neo-Synalar Cream rarely produces allergic reactions.

College Yield to Stay High, If Business Helps

It's called one of the shrewdest investments business ever made—the college contribution. It has paid the best dividends business ever got—the 42% of college-educated leaders that business employs, every year.

A real human potential. Leader stuff. Bright with brainpower, brimming with skills. Able to fill management posts.

But can it go on, can the colleges guarantee the supply?

Higher education is in

trouble. Costs are skyrocketing. On the average, tuition fees cover only about 1/3 of the educational cost. What is needed? More business giving. Unrestricted giving. Business can gain even more by raising the quality of education to an all-time high.

If business wants college talent, it must help keep the colleges in business.

Your aid-to-education program is an aid to yourself.

Medical Seminar

Pregnancy Associated with Heart Disease

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

THE CONSIDERATION of heart disease associated with pregnancy has increased in importance within the past two decades. This is the net result of several factors, which include a decreasing incidence of therapeutic abortions formerly considered to be justified, an increase in the number of children who survive rheumatic fever, subacute bacterial endocarditis, and congenital heart defects, and the better control of infections, anemia, and toxemia. Today, heart disease is one of the leading causes of maternal morbidity and mortality.

According to the New York Heart Association,¹ diseases of the heart "... are here considered to include not only the structural changes found in the heart, pericardium and adjacent arterial structures but also such disturbances of the functions of the heart as are manifested by arrhythmia, by its ability to perform its function as a pump and by its tendency to give rise to abnormal sensations." The Association has further devised a widely used system of complete cardiac diagnosis, utilizing the following terms: etiology, anatomy, physiology, and class (functional and therapeutic).

In several large series²⁻⁷ reported since World War II the incidence of heart disease associated with pregnancy has varied from 1 to 3.7% (Table 1). These reports indicate that more than 80% of cardiac problems associated with pregnancy are of rheumatic

origin; congenital and hypertensive heart diseases account for most of the remaining 20%.

More than 75% of rheumatic heart disease is mitral valve disease; another 10 to 15% is combined mitral and aortic disease.

A number of other types of heart disease are occasionally encountered in pregnancy and should be kept in mind. These include kyphoscoliotic* cardiac changes,⁸ subacute bacterial endocarditis, acute rheumatic fever, cor pulmonale, myocarditis (luectic, tuberculous, idiopathic), cardiovascular syphilis, chronic constrictive pericarditis, and Marfan's syndrome.⁹ In addition, a physician should always be prepared to handle a cardiac arrest.

Physiology

Perhaps the fundamental concept to keep in mind is that pregnancy is a complication of heart disease; the latter remains the primary problem and must be treated with full knowledge of those cardiovascular and respiratory changes that accompany pregnancy. The point to be made in the following discussion is twofold: first, the work of the heart in pregnancy is increased, and second, there are many normal physiologic changes that mimic the abnormal changes found in the pregnant cardiac patient.

Plasma and Red-Cell Volume

Both the major components of blood, the

Continued

*See Test Your Word Score Page 687.

red cells and the plasma, may be measured by the dye-dilution principle. Neither Evans blue nor radioactive iodinated serum albumin (nor any of the several other tracers used) cross the placental barrier; so measurements are of maternal plasma only. Red-cell volume may be measured by the same principle, by the labeling of a sample of the subject's blood with ^{51}Cr or ^{32}P .

From their extensive survey of the literature from 1938 through 1963, Hytten and Leitch¹⁰ arrived at the best estimates they could make for the increase in plasma and red-cell volume. These two components need only be added together to give the best estimate for total blood volume, which they conclude increases by 20 to 40%, with the maximum occurring from the thirtieth through the thirty-fourth week of pregnancy (Table 2). The validity of this statement has recently been questioned by Pritchard¹¹ (as well as others) who reported that he found no decrease in blood volume during the last weeks of pregnancy.

Body Water

Total body water increases throughout pregnancy, the amount being approximately 20% above normal at term. The mechanism of this increase has not been well established, but it appears to involve some, or all, of the following factors: sodium retention, increased plasma volume, depression of the glomerular filtration rate, decrease in concentration of serum proteins, and the action of estrogen and progesterone on the renal tubule.

Edema in the absence of preeclampsia or organic heart disease is common during the latter half of pregnancy and has been attributed to lymphatic and venous obstruction by the enlarging uterus, reduction in plasma osmotic pressure, and retention of water and sodium. As plasma volume increases, blood viscosity decreases and circulation time is prolonged.

The Blood Cells

The red cell itself apparently is changed
